nervous disease in her family. She has two children, who are in good health. I ought to mention that the contraction mentioned by Mr. Proffitt as occurring after the accident disappeared completely, and that before her visit to Llandudno she could walk quite well. On admission she appeared a well-developed, well-nourished young woman. She has a fair, fresh complexion, with light hair and blue eyes. She lies mostly on the right side, the knees flexed, with the feet extended. She reads and does crochet work for her amusement—both, she tells us, as well as ever. Her temperature is normal; pulse 84, regular and full; respiration 20. The heart, lungs, liver, and spleen are normal. Menstruation occurred normally ten days before admission. The bladder and rectum perform their functions regularly and without pain. The urine is acid, sp. gr. 1022, contains a faint trace of albumen and a large quantity of indican, and it deposits phosphates and vaginal epithelium; the daily quantity is from forty to fifty ounces. Her intelligence and special senses appear to be unaffected. The fundus of both eyes is normal; there is no colour-blindness or loss of pupillary reflex to light. She protrudes her tongue well, but it is distinctly tremulous. Her sensation to touch and pain seems everywhere undiminished. There is some hyperæsthesia of the skin of the trunk, and great hyperæsthesia of the muscles of the lower extremities, great pain being apparently caused by grasping the calf muscles of either leg. The spine is normal to sight and touch, and is not tender anywhere. The upper extremities are quite normal, though some time ago there was some numbness of the left hand. At present sensation, motion, and electrical reactions are quite normal. There is no tendency to drop-wrist. The lower extremities are usually flexed and adducted, the feet, however, being always extended in the talipes equinus position. She can flex and extend the thighs upon the abdomen, and flex the legs on the thighs, but she cannot extend the legs beyond an angle of 120°, nor can this be done by employing any reasonable amount of force, while the attempts cause acute pain. In both popliteal spaces there is a mass of œdema the size of an orange. The anterior muscles of the thighs are wasted. There is no patellar reflex. The muscles of the legs are wasted, and the calf muscles are very flabby. She can extend her toes very feebly, but has no power of moving the ankle-joints, nor can they be dorsiflexed by passive movement, though they move laterally quite readily. The skin of the feet is moist with perspiration, and on their inner aspects there is a papular rash, which looks like hyperæmia of the sweat glands. She complains of alternate feelings of heat and cold in the feet. The whole of the wasted muscles show loss of faradaic contractility. Their galvanic excitability is much diminished, but not altered—that is to say, the kathodal stimulus is still greater than the anodal. The use of the constant current appeared to cause great pain. The cutaneous reflexes are all present; there is no ankle clonus, and patellar reflex, as already stated, is quite absent in both legs.

This patient is clearly suffering from atrophic spastic paralysis of the lower extremities; but we must go a step further, and inquire what is the pathology of the disease—what is the seat of the lesion, and what is its nature. The wasting and loss of electrical reactions of the muscles, with the absence of patellar reflex, are the great features of the case, and these enable us at once to exclude hysteria, which may present a perfect picture of ordinary spastic paraplegia. There is also absolute want of any evidence of hysteria in the history or manner of the patient. The distribution of the paralysis in the lower extremities, and the absence of any cerebral symptoms justify us in looking lower than the encephalon for the seat of the lesion. Spinal meningitis or a transverse lesion of the cord would cause pain, anæsthesia, bladder and rectum troubles, or bedsores, none of which are present. If it is a spinal affection, it must be what is called a systemic lesion, picking out and attacking certain anatomical elements only of the cord. A lesion of the posterior columns does not at all fit the case, as we should not expect to find wasting, paralysis, loss of electrical reaction in the muscles, or rigidity of joints; while we might expect girdle pain, loss of pupillary reflex, and some anæsthesia. But it is not so easy to dismiss the suggestion that the lesion may be seated in the anterior horns of grey matter, extending to the adjacent white columns. Acute anterior poliomyelitis is familiar to you as the cause of the essential paralysis of children, but the same disease occurs sometimes, though not nearly so frequently, in adults. We know that it is characterised by paralysis, rapid wasting of muscles, loss of electrical contractility, followed by contractions and loss of tendon reflexes. But before we decide to accept this explanation, I would like to sketch for you the clinical picture of alcoholic paralysis, as it has been described by recent writers, and which, perhaps, does not find a place in the text-books you have read.

The earliest account of alcoholic paralysis, according to Dr. Dreschfeld, was by Dr. Jackson of Boston in 1822, but the first European writer on the subject was Dr. Magnus Huss of Stockholm, in 1849. Later on, Lancereaux and Leudet in France, and Wilks in England, recognised and wrote upon this disorder. Dr. Wilks mentions it in his Lectures on Diseases of the Nervous System, published in 1878. Within the last few years a good many cases have been published, and much has been learnt respecting its clinical history and pathology from the writings of Glynn, Broadbent, Déjérine, Hun, Dreschfeld, and others. It is also described in Dr. Ross's recent Handbook of the Diseases of the Nervous System (J. and A. Churchill, 1886), and it is now established as a form of paralysis, with definite clinical history, symptoms, and morbid anatomy.

Alcoholic paralysis occurs chiefly, but not always, in females, and according to Charcot (though I think this is doubtful) only in those with neuropathic tendencies—of course, too, only in those who indulge in immoderate and prolonged abuse of alcohol. Its onset is gradual, commencing with pains in the legs and some loss of power. The patient walks with uncertain gait, using a stick or helping herself by the furniture, and in this stage there is a strong resemblance to locomotor ataxy, which is strengthened by the loss of the tendon reflexes. There is usually some anæsthesia or hyperæsthesia, and a very marked symptom is *the hyperæsthesia of the muscular masses*. The paralysis affects chiefly the extensors, and is followed by wasting and loss of electrical contractility, with, we are told, perversion of the normal galvanic excitability, the anodal stimulus equalling or exceeding that of the kathode. Vaso-motor disturbances, œdema, cutaneous eruptions, and sensations of heat or cold are often present in the affected limbs. The upper extremities may be attacked, the earlier signs being numbness and a tendency to drop-wrist. The researches of Déjérine and Moeli have proved that the brain and spinal cord are intact, the lesion being seated in the peripheral nerves. Up to quite recently this lesion was said to be what is called Wallerian degeneration, named after a former distinguished teacher of this school. It is identical with the changes seen in the peripheral part of a nerve two months after it has been divided. These are disappearance of the axis cylinders and breaking up of the myelin or medullary sheath, which runs together to form globules, the outline of the nerve tubes becoming irregular or moniliform. Recently M. Gombault has described the primary lesion of the nerve as an inflammation of the myelin, which becomes granular with its nuclei increased, while the axis cylinder remains intact. To this lesion he gives the name of "periaxial segmentary neuritis." The Wallerian degeneration occurs as a result of this lesion.

It will be at once admitted that our case presents in most particulars a striking resemblance to this description. But there are three points in which it does not altogether conform, and I must not omit to point these out to you. You will recollect that our patient ascribes her illness to a chill caught while bathing. I do not think we can accept this statement as complete evidence, but it must go for what it is worth. In the second place, she speaks of the shock as occurring suddenly, and though Mr. Proffitt's account shows that the loss of power was gradual, yet she fixes a very precise date to the occurrence of the first symptoms in a manner that does not agree with the usual mode of onset as described by writers on alcoholic paralysis. Lastly, we have contractures and rigidity of the knees and ankles. It is admitted by some writers that contractures may occur, but they are very exceptional, and, as a general rule, their presence should make you hesitate to accept a diagnosis of peripheral paralysis.

All modern writers speak of the reaction of degeneration as present. By this they mean that the contraction obtained on stimulating the muscle with the galvanic current is greater on anodal (positive pole) than on kathodal (negative pole) closure, or, as they express it, A.C.C. is greater than K.C.C. I tested this point very carefully, and found that, while galvanic excitability was certainly diminished, no qualitative change existed; and I would take this opportunity

of telling you that in my experience this much-talked-of sign is neither certain nor trustworthy. The great pain complained of from the use of the galvanic current was probably due to the hyperæsthesia of the muscles giving rise to painful spasms when contracting; the faradaic current, which is ordinarily much more painful, failing to excite the muscles at all, caused no complaint.

After duly weighing all the evidence, and allowing full consideration to the facts just stated, I have concluded that a diagnosis of alcoholic paralysis is the most consistent and most tenable. My experience of this disease is limited to two other cases. One I saw only once in consultation with my friend Dr. Drummond of this town. She was an old woman living by herself as landlady of a small beer-house. She had an enlarged liver and bronchitis, and, I heard, died not long afterwards. The other was a young woman who was admitted into this hospital under my care, and who made a very speedy recovery when removed from all possibility of procuring alcohol. Neither of them afford any information which can throw light upon the present case.

I would draw your special attention to the diagnostic significance of the painfulness or hyperæsthesia of the muscular masses. I cannot assert that this symptom is absolute proof of alcoholism, but it is of the highest value in directing your suspicions in that direction. The vaso-motor disturbances, sweating œdema, &c., are also of importance, and are well marked in this case. The presence of a large amount of indican in the urine is not of special importance. We look for it usually, and find it frequently, in association with torpid action of the bowels. Indican is derived by oxidation from indol, a product of the pancreatic digestion of albumen. It is absorbed from the intestine into the blood, and excreted by the kidneys.

I can only speak very doubtfully about the prognosis. Between such happy examples as Dr. Wilks gives, such as was my patient of last year, and those fatal cases recorded by Dr. Broadbent, there must be a long intermediate series. I consider the presence of contractures to be most serious in view of the prospect of our patient regaining the use of her limbs. We have tried without success to remedy the faulty position by extension and massage. Besides these means, our treatment has included galvanism and, for internal medication, strychnia in gradually increasing doses. She has shown great tolerance for this drug, as she is now taking twenty minims of solution of strychnia three times a day without inconvenience, and I must add without much benefit, although her general appearance has considerably improved since admission.

AN EASY METHOD OF DISTINGUISHING THE SOLUTIONS OF CARBOLIC ACID USED IN SURGERY.

By MATTHEW HAY, M.D.,
PROFESSOR OF MEDICAL JURISPRUDENCE, UNIVERSITY OF ABERDEEN.

SINCE the epoch-making introduction of antiseptic surgery by Lister, carbolic acid has continued to maintain its position of supremacy as the best of all antiseptics for general surgical purposes. Though it has been shown to be by no means the most potent of the antiseptics, yet it possesses various advantages in surgical use which the more active members of this important pharmacological group are without. It has been hard pressed now and again by new competitors for the favour of surgeons, and in some hospitals has been for a while almost completely driven from the field; but in nearly every case, after a longer or shorter time, it has been reinstated in its old place. It is somewhat curious to observe, in this age of scientific progress, when every year is adding enormously to our knowledge of organic compounds, both from the chemical and the therapeutical standpoint, that in the two most surprising and important advances in practical medicine which this century or any other has seen—viz., antiseptic surgery and anæsthetic surgery—those substances which were originally used in connexion with these methods of operative treatment should still hold the foremost place they do. It is admitted on all sides as extremely probable that a more perfect and generally useful antiseptic than carbolic acid is discoverable, and it is equally freely admitted that it is possible to find a more safe and reliable anæsthetic than chloroform and ether; yet, in spite of many worthy attempts, these substances have not yet to any large extent been supplanted. It may be that prejudice inclines us to the use of the substances which are so bound up with the origin of these advances. But I think it may be more true to say that the great care with which Lister chose his antiseptic and Simpson and his fellow-workers their anæsthetic did away with any probability of better agents being discovered for many years to come. It is thus greatly to their credit that the substances they first employed are in use still. This smaller credit is of course completely overshadowed by the greater which attaches to the discovery of the principle or the method.

This is a needless digression, unless it be to show that, as carbolic acid has not yet been displaced as an antiseptic, and may not be for some years, the immediate subject of this communication is not likely to lose its value so soon as published. The two strengths of the solution of carbolic acid in common use among those who practise antiseptic surgery are, as everyone knows, one of the acid in twenty parts of water (or a 5 per cent. solution), and one in forty parts (or a 2½ per cent. solution). These solutions are used for somewhat different purposes, and I take it that it is generally of some importance that the one should not be substituted for the other the more so, as carbolic acid is not a very powerful antiseptic, and moderate dilution of it annuls its action. Now, as labels will drop off occasionally, or even the apothecary may supply by accident the weaker instead of the stronger solution, it may be sometimes desirable to be able to readily distinguish the solutions. The surgeon can thus have some check on the possible caprice of the dispenser, and begin his operation with the same confidence in the fitness of his weapons that the soldier possesses when he enters battle, knowing that his rifle or sword has recently withstood the armourer's test. The reagent which I have to propose for the distinction of the solutions is a saturated solution of chloride of sodium. If such a solution is added in about equal quantity to a 5 per cent. solution of pure crystalline carbonic acid, the mixture becomes milky and opalescent, and the milkiness does not disappear on shaking; whereas, if added to a 2½ per cent. solution, the mixture remains perfectly clear. The opalescence is due to the separation of carbolic acid in the form of minute drops. Chloride of sodium has a greater affinity for water than carbolic acid has, hence it is capable of displacing carbolic acid from its solution. This happens, however, only when the solution of carbolic acid is of sufficient strength. Otherwise they remain side by side in complete solution. In preparing the saline solution, it is preferable to use the pure crystalline sodic chloride employed in laboratories. This is quite a cheap substance. The advantage which this possesses over many of the ordinary varieties of common salt is that it forms a perfectly clear solution on being shaken with water, even though a large amount of undissolved salt be still present, the crystals quickly sinking to the bottom of the vessel in which the solution is being made. On the other hand, a solution of ordinary salt has often a muddy appearance, which only disappears after filtration or long standing. There is no other objection to the use of ordinary salt. The saturated solution can be prepared in quantity and kept at hand as an ordinary reagent, or it can be prepared each time as it is required. A small quantity can be made in less than two minutes, by placing some of the crystals in a test-tube, adding about an equal bulk of water, and shaking vigorously, slightly heating to 40° or 50° C., then cooling under the stream from a water-tap, still shaking, to about 15° C. (60° F.). The heat facilitates the solution without very appreciably increasing the amount of the dissolved salt as compared with that dissolved at the ordinary atmospheric temperature. It is a peculiarity of common salt that its solubility is very slightly raised by heating. It is essential to cool the solution before mixing it with the carbolic solution, for, if it be hot, the carbolic acid will not be precipitated but will remain in solution. It is needless to give directions for the preparation of the salt solution in bulk; it can be done in the usual way. It is only necessary to keep the bottle containing it in a place where its temperature is not likely in winter to be reduced to very near the freezing point; otherwise the strength of the solution may be weakened by the deposition of the salt.

In performing the test, it is advisable to add the carbolic solution to the salt solution—say in the test-tube,—not the

salt solution to the carbolic solution. If the addition be made slowly, drop by drop, it will be observed that each drop produces a small white cloud of separated carbolic acid, which disappears at once with a single shake of the test-tube until the carbolic solution added is equal to about one-fourth part of the salt solution, when the separated acid no longer disappears on shaking. With every further addition of the carbolic solution the amount of separated acid increases, the fluid meanwhile becoming more and more opaque. The density is greatest when from three-fourth to four-fifth parts of the carbolic solution have been added to one part of the salt solution. With further addition of the solution the acid begins to be redissolved and the milkiness to disappear, and the mixture becomes almost perfectly transparent when about two parts of the solution have been added. I have thus described in detail the progress of the changes observed in mixing the solutions with the object of emphasising the need of mixing them in proper proportion. If either too little or too much carbolic solution be added to the salt solution no permanent precipitate of the acid will be obtained. Further, if the temperature of the mixture is above 23° or 24° C. (74° F.), the carbolic acid remains in solution, the solubility of the acid rapidly increasing with the rise of temperature. Should it happen, as it rarely does in this climate, that the temperature of the room is above 24° C., the mixture can be readily cooled by tap-water, or by the evaporation of a few drops of ether or alcohol on the outside of the test-tube in which the mixture is placed. It is necessary, in performing the test, to use test-tubes or glasses which have been previously well dried. A residue of water in the test-tube may prevent the reaction, as will be made evident immediately. It may be well to remark that, on adding a 2½ per cent. solution of carbolic acid, a slight haziness is sometimes perceptible as a drop falls into the salt solution, but this instantly disappears.

The question now naturally arises how far can a 5 per cent. (1 in 20) solution of carbolic acid be diluted before it ceases to give the reaction? It is interesting to find that the addition of quite a small quantity of water is enough to prevent the reaction; that is, no separation of carbolic acid is obtained which does not disappear on slight shaking. For it always happens that when the stronger solutions of carbolic acid are employed, they give as each drop falls into the saline solution a distinct cloud, but this is at once dissolved on being diffused by shaking through the mass of the mixture. If the strength of the solution be lowered to 4·6 per cent. (1 in 21·7), the reaction is not obtained unless the temperature of the mixture is below 8° or 9° C (47° F.); if lowered to 4·5 per cent., the reaction fails unless the temperature is below 4° or 5° C. (40° F.) A 4·8 per cent. solution gives the reaction quite distinctly, though less so than a 5 per cent. solution, unless the temperature is beyond 18° C. (64° F.) Hence, only a solution of greater strength than about 4·8 per cent. (1 in 20·8) can be trusted to give the reaction at the ordinary average temperature of the atmosphere in this country. A solution weaker than 4·5 per cent. (1 in 22·2) will not give the reaction, though the temperature approach zero. It happens frequently that, for convenience, chemists prepare the carbolic solutions from liquid carbolic acid—that is, acid containing usually about 10 per cent. of water; and at least one of the best known makers of the acid states on the label affixed to the bottle that, in dispensing the acid, the water may be disregarded. If chemists follow this instruction, and a 5 per cent. solution be prepared by *weight*, it will contain only 4·5 per cent. of pure acid, and will therefore not give the above reaction. If it be prepared by *volume*, as is likely in many cases, then, as the specific gravity of the liquid carbolic acid is greater than that of water, being about 1068 (I found one specimen of Calvert's to be 1070), a solution of greater strength is obtained, containing about 4·82 per cent. of acid, and therefore of sufficient concentration to give the reaction. It is thus quite easy to distinguish by means of the reaction carbolic solutions made from liquid and from crystalline carbolic acid, if both have been made by weight.

If it is desired to render the sodic chloride solution more sensitive, it can be readily done by saturating it with carbolic acid. I find that a saturated solution of the chloride at 15° C. is still capable of dissolving carbolic acid to the extent of about 0·95 per cent., or, roughly, 1 per cent. Such a solution is best prepared by dissolving the salt to saturation in a 1 per cent. solution of carbolic acid. When the solution has become fully saturated, it will have a hazy appearance, from the separation of a little carbolic acid; this can be readily removed by filtration. If this solution be used instead of the simple salt solution, then it will be found to precipitate the carbolic acid more freely than the other, and, in the case of solutions stronger than 4·5 per cent., at any temperature under 32° to 35° C. (93° F.); but this increase in the sensitiveness of the reagent is gained at the expense of diminishing its value for the purpose of distinguishing carbolic solutions slightly weaker than 5 per cent. from those which are stronger. The reagent is now capable of precipitating carbolic acid in any solution stronger than 3½ per cent. In solutions weaker than 3 per cent.—therefore in a 2½ per cent. (1 in 40) solution—no precipitate is formed, or, if it is, it at once disappears on shaking. If the surgeon wishes merely to possess a reagent which will readily, and at any ordinary atmospheric temperature, enable him to distinguish a 5 per cent. from a 2½ per cent. solution of carbolic acid, the carbolised salt solution is decidedly preferable to the simple salt solution.

There is still another way in which chloride of sodium may be employed—viz., for the distinguishing of very strong and very weak solutions of carbolic acid—not the usual surgical solutions. It depends on the fact, which I have ascertained, that while a perfectly saturated solution of the salt is still capable of dissolving about 1 per cent. of carbolic acid without separation or displacement of the salt, yet a perfectly saturated solution of carbolic acid cannot dissolve more than the fragment of a crystal of the salt without the acid beginning to separate. Hence, if, on dissolving a small crystal or two of common salt in a solution of carbolic acid, the fluid becomes opalescent, and the opalescence does not appear on shaking, the solution is a saturated one—that is, it contains about 7½ per cent. of acid. If, on the other hand, no opalescence appears, not even when so much salt has been dissolved in the carbolic solution, by shaking and slight heating and subsequent cooling, as that the solution has become saturated with the salt, then the original solution contains less than 1 per cent. of acid.

It is perhaps desirable, in conclusion, to briefly summarise the contents of this communication. The three reagents suggested are:—1. A saturated solution of chloride of sodium. This precipitates carbolic acid from solutions stronger than 4·8 to 5 per cent. at a temperature not exceeding 18° to 24° C. (64° to 75° F.). It causes no permanent precipitate in weaker solutions. 2. A carbolised saturated solution of carbolic acid. This precipitates carbolic acid from solutions stronger than 3½ per cent., and it does so, in the case of solutions above 4½ per cent., at any temperature below 32° to 35° C. (90° to 95° F.). It gives no permanent precipitate with weaker solutions. This is the best reagent for the simple distinction of the usual surgical solutions—2½ and 5 per cent. 3. Solid chloride of sodium. A small crystal of this precipitates carbolic acid from a saturated solution; whereas, when dissolved even to saturation in a weaker carbolic solution than 1 per cent., it gives no precipitate.

CASE OF SUPRA-PUBIC LITHOTOMY.

REMOVAL OF A STONE WEIGHING 24½ OZ.; RECOVERY.

BY THOMAS SMITH, F.R.C.S.,

SURGEON TO ST. BARTHOLOMEW'S HOSPITAL.

W. K——, an artilleryman, aged forty-three, was admitted into St. Bartholomew's Hospital on April 14th, 1886. He had served as a soldier in India and throughout the Abyssinian campaign, and was engaged in his military duties until a week or two before admission. For the last ten weeks he had passed his urine more frequently than usual, rising five or six times by night for this purpose. More recently he had been unable to retain his urine completely, especially when lying down. He has always micturated in a good stream, and without difficulty or pain; he never passed any blood, but for some time he had observed a little shreddy mucus in the urine. The only inconvenience he was suffering from was increased frequency of micturition and some slight pain over the pubes. He had never been sounded. The urine was neutral, sp. gr. 1010; it contained a trace of albumen and a little flocculent mucus. About fifty ounces was passed in the twenty-four

hours. He is a large-framed man, of spare habit and fairly healthy appearance.

On examining through the rectum, a densely, hard, rounded swelling could be felt in the situation of the prostate; on the first examination it was thought to be a tumour growing in the prostate, and it was not until an anæsthetic had been given and a sound introduced that its real nature was ascertained. It was found to be slightly movable, and could be felt between the finger in the rectum and the hand over the pubes. The sound would not enter the bladder, but readily struck the stone at the vesical orifice of the urethra.

For a short time the bladder was washed out daily with a boracic acid solution, and on April 22nd the supra-pubic operation was performed. The urine being drawn off as far as possible with a red rubber catheter, about ten ounces of the boro-glyceride solution were injected and a tape tied round the penis; this proceeding brought the bladder into such prominence above the pubes that the use of the rectal bag was dispensed with. An incision four

Exact size of stone. Weight 24½ oz.

or five inches long was made in the mesial line and the bladder exposed at the lowest part, all bleeding vessels being secured as they were divided. All veins in the immediate neighbourhood of the incision were also tied and divided, especially those in the loose tissue behind the pubes. The abdominal wound being held widely open by retractors, all tissues down to the level of the bladder were pushed upwards and held by a blunt double hook. The bladder was first opened at the lowest part, the wound being enlarged to the extent of four inches by a probe-pointed bistoury. The bladder wound was held apart by retractors, so that its cavity was widely opened and the stone freely exposed. The muscular wall of the bladder was much hypertrophied, being three-quarters of an inch in thickness; it bled pretty freely when divided. The stone, which was somewhat disc-shaped, lay in the middle line, with its broad surface upwards, and fitted closely the surrounding parts. On making pressure from the rectum, the stone revolved so as to present its thinner edge and to allow the insertion of large lithotomy forceps. It was extracted with very moderate force. The mucous membrane of the bladder presented a healthy appearance; it was neither ulcerated nor abraded. The bladder wound was closed with seven deep sutures of carbolised silk, passing through the whole thickness of the muscular substance, and six or seven more superficial sutures of carbolised catgut. A space was left just above the pubes for the introduction of a red rubber catheter, and this was tied in, one end protruding at the abdominal wound, the other being carried out through the penis; several holes were cut in that part of the catheter which lay in the cavity of the bladder. The upper two-thirds of the abdominal wound was closed with silver sutures, the whole surface was dusted with iodoform, and the cavity behind the pubes was filled with small pieces of sponge separated from the wound surface by carbolised oil lint, so as to stop all oozing of blood; the whole was covered with iodoform gauze.

For a few hours after the operation it was necessary to syringe pretty frequently through the abdominal end of the catheter to keep it free from blood-clots; afterwards this was done twice a day. The patient suffered scarcely any pain after the operation and during his convalescence, except when the wound was dressed. That part of the abdominal wound which was sutured united at once. The bladder wound, so far as could be seen, did not unite at once; the lowest part of this wound and that in the abdominal wall were evidently bruised by the retractors; their surfaces separated in shreddy sloughs, and retarded convalescence so far as the healing of the wound went. The temperature rose once to 102° on the second day; next day it fell to 100°; and after a week it became almost normal, and remained so throughout. On May 13th the patient was able to leave his bed, and two days later the catheter was removed. On the 22nd he went out of doors. On June 1st he went back to bed, and had a catheter tied in, as there was still a sinus open above the pubes, which could be kept closed by plaster drawn across the abdomen for days. On July 16th the edges of the wound were pared, silver sutures introduced, and a catheter tied in.

The stone removed weighed 24½ oz.; it was ovoid in shape, and consisted of phosphates externally, with a large oxalate nucleus. On section it was found to be dense in structure, and regularly laminated. It was certainly a heavy stone for its size. The accompanying illustration is drawn to scale, and represents exactly the transverse and longitudinal diameters; it measured 13 in. in its largest circumference, and 9½ in. in its smallest.

The above account has been given somewhat in detail, since there is need of a larger recorded experience of supra-pubic lithotomy to determine certain points of practice, both in the actual performance of the operation and in the after-treatment. The unusual size of the stone enabled me to dispense with the use of the rectal bag; the pelvic portion of the bladder being occupied by the stone, a very moderate distension with fluid sufficed to bring the bladder into prominence above the pubes. The wound in this case was of necessity very large. The extra space was gained by increasing the length of the incision rather than by any transverse division of the tendons of the recti muscles, and it is an open question which proceeding least impairs the strength of the abdominal wall. The veins in the loose fat behind the pubes were tied and divided, as possibly giving greater security against secondary hæmorrhage—an accident which has been known to occur in more than one instance. The bladder was sutured after Petersen's method, the wound being closed, except at its lowest point where space was left for the introduction of a catheter. It is doubtful if this be the best plan to adopt; Sir H. Thompson, whose experience of the hypogastric operation since its revival is the largest on record, does not employ any suture at all, and, as I understand, has met with no difficulty in the closing of the wound. Such difficulties, however, do occur. In my own case three months after the lithotomy, I closed

a supra-pubic fistula with silver sutures. In Mr. Barwell's case the wound was as long as three months in completely closing; and lately I heard of a patient who was admitted into Professor Billroth's wards for a fistula the results of a supra-pubic operation performed eight months before. Mr. Robert Parker has recently recorded a case of suture of the entire wound in the bladder followed by immediate union; and he suggests that in young subjects, where the tissues are healthy, an attempt to secure primary union should be made by carefully suturing the bladder. It would be greatly to the comfort of the patient if the bladder wound could be closed at the time of the operation, and it is to be hoped that a larger experience may lead to improvements in this respect. In the case here recorded the bladder wound was little likely to have united even if entirely closed by sutures, since the edges were of necessity somewhat roughly treated, owing to the size of the stone. Yet it seemed to me possible that the wound would never have united if left entirely unsutured; it was four inches in length, and without some sutures the edges could easily have overlapped and made union almost impossible.

With regard to the size of the stone. I believe this to be the largest that has been extracted during life, and certainly it is the largest that has been removed with complete recovery of the patient. Very few larger calculi have been removed after death. Professor Humphry and Mr. Holmes have recorded instances of calculi removed after death—one weighing 33 oz., the other 25 oz. Mr. Rivington extracted a stone almost as large as in the case here recorded; but his patient did not ultimately survive, though he recovered from the operation. In Sir Henry Thompson's case the stone weighed 14 oz., and the patient completely recovered. Dr. Rutherford Morrison has recently recorded a case where he removed a stone weighing 22½ oz., the patient dying on the thirteenth day.

The almost complete absence of the characteristic symptoms of stone in this patient was a remarkable feature in the case, though in this respect it does not stand alone, for in other instances of very large calculi the same peculiarity has been observed, though in a far less degree.

Stratford-place, W.

CHILDBED FEVER; ITS CAUSES AND PREVENTION: A LIFE'S HISTORY.

By THEODORE DUKA, M.D., F.R.C.S. Eng.

(*Concluded from page 208.*)

THE third great man who spoke out for Semmelweis was Skoda; not heeding unpleasant occurrences, he stood firm by what he considered right. Strange to say, as long as Semmelweis was content to labour in a subordinate position as assistant to Dr. Klein, he was left undisturbed in carrying out his efforts of improvement; but the moment his views had become a topic of public attention, and particularly when Semmelweis's name was spoken of by others, the aspect of affairs regarding him took a different turn. Not only himself, but his friends, and particularly Skoda, became objects of malevolent attacks, especially when it was proposed by the latter that a commission should be appointed to investigate and report upon Semmelweis's treatment; to this the professors agreed, and the members named. Dr. Klein, however, entered a protest against these proposals, and the Government was moved to forbid further proceedings. Semmelweis hereupon simply remarks that this step against himself on the part of his master "remains unaccountable." Dr. Bruck, however, does not hesitate to stamp the interference as "narrowminded and petty, the probable outcome of selfishness and vanity." "At that time," says Dr. Koranyi, "there were really two schools at Vienna: one was the official school, which sat in easy chairs, but of which the outer world knew nothing; the other school was that which made a mark on the period of its existence, but it was placed in the background, and worked quietly in the cliniques and laboratories; the scientific world followed these labours with sympathy." Skoda went so far as to make an urgent appeal to the Academy of Medicine of Vienna, by reading a most important paper on the subject. In it he enumerates facts and conclusions which were the natural outcome of Semmelweis's labours. The Academy approved Skoda's speech, and caused it to be embodied in the *Sitzungs Berichte* for October, 1849. Separate copies of it were ordered to be printed and widely circulated. Skoda mentioned also the necessity of certain experiments to be performed on animals; the Academy at once made a grant of 200 florins for Semmelweis and Bruck to carry them out.

The important communications of Hebra, Haller, and especially of Skoda, awakened a profound interest throughout the profession. An important discussion ensued, in which Scanzoni, Kiwisch, and Seyfert took part; these denied all importance to Semmelweis's discoveries. Scanzoni especially contended that the cause of puerperal fever is to be sought in atmospheric conditions. From this it was evident that the opinion enunciated by several authorities was not as favourable to Semmelweis's views as was expected. The disappointment he felt keenly, because the impulse to his investigations was his warm sympathy with the sufferers. He was not a literary man, as he more than once expressed, and never cared to appear in the press; but when he saw that the number of his opponents was on the increase he was urged by his friends, and even officially requested, to deliver a discourse before the Medical Association in defence of his opinions. The meeting was held on May 15th, 1850, and continued over three sittings; at the invitation of the President, Dr. Rokitansky, a discussion followed; the objections of Scanzoni, Seyfert, and Kiwisch were refuted one by one. Referring to the report in the *Zeitschrift*, Jahrgang vi., Bd. ii., and Jahrgang vii., Bd. i., we find that Chiari, Helm, Arneth, and Hayne supported, whilst, on the other hand, Zipfl and Lumpe opposed, Semmelweis; the latter speakers particularly called in question his statistics. The result of the discussion was, on the whole, favourable to the lecturer. We find in the "Transactions" Dr. Herzfelder stating that "Semmelweis's discoveries were to be looked upon as a triumph to scientific inquiry, and that the objections of Zipfl, Lumpe, Seyfert, and Scanzoni had been entirely disposed of by Semmelweis." But the triumph thus gained has not been followed up. Semmelweis, unfortunately, omitted to publish his paper; the short reports of the secretariat, though correct enough in the abstract, were insufficient in substance, and could not cope with the carefully prepared and widely circulated communications of his opponents; and the opinion found favour in the profession that, in addition to actual poisoning by decomposing animal substances, there must be "something else" to account for epidemic occurrences of puerperal fever. This "something," however, was the *ignotum quid*, the unknown agent.

Semmelweis was not satisfied with the partial concession to his doctrine; he would insist upon the absolute necessity of using disinfectants, and under no circumstances would he allow a patient to be examined unless with perfectly clean hands. Under such conditions it was essential not to spare any effort in advocating the new doctrine. Adverse circumstances prevented this being done. When the memorable three days' discussion before the Medical Society took place Semmelweis was no longer a member of the medical staff of the Vienna Hospital. His two years' tenure of office had already expired, and an application that his appointment should be extended was not acceded to; this was the more galling to Semmelweis, as his opponent, Dr. Braun, was allowed to retain a similar post in the other clinique. On the 20th of March, 1849, Semmelweis had to relinquish the field of his labours, and even the humble request of being allowed to establish himself as a *privat docent* connected with the University was negatived by the authorities. Nothing daunted, he made another trial to obtain his end, and, after waiting eight months, he was gazetted as a *privat docent*, but with the strange proviso that no demonstration would be permitted on the living body. This unexpected restriction Semmelweis looked upon, very justly, as a personal slight; yet, for the sake of the cause he had so much at heart, he would probably have accepted his position if fresh annoyances had not rendered his stay in Vienna intolerable. He left the Imperial city for good, returned to Hungary, his native country, and established himself in Pesth. The cause of the unworthy treatment which drove Semmelweis away from Vienna was due, according to Dr. Fleischer, to political circumstances which unhappily prevailed at that time, and influenced the medical profession as well. His sudden departure from Vienna in October, 1850, marks a turning-point in Semmelweis's life history. The unfair treatment experienced at the very place where he justly hoped for appreciation and

reward embittered his mind, so that the very wish for further exertion seems to have been crushed in him. He remained indifferent as to the fate of his discoveries just at the very time when it seemed so important to propound them by word and writing.

Smarting under keen disappointment, and finding his own native land desolate and suffering under the recent national disaster, Semmelweis remained silent for years. This silence was almost fatal to the furtherance of his own opinions, which, as all knew, shook the old doctrines to their very foundation, and therefore produced passionate opposition. Semmelweis's exertions and the advocacy of his friends seemed to come to nothing; the battle-field was left in the possession of those who maintained that outbreaks of puerperal fever were solely due to epidemiological causes. The period between 1850 and 1860, which Semmelweis spent at Pesth, was a period of deep mourning of his defeated nation. The foreign military authorities looked with suspicion on the smallest sign of life, social, scientific, or political, among the Hungarians. The author's pecuniary resources had, moreover, been exhausted during his life in Vienna. After arriving in Pesth, his great object was to be attached to one of the cliniques, and he was the more anxious in this respect because he was informed that, owing to the same causes that prevailed at Vienna, the maternity department of the Hungarian University had to be closed twice in a single year. After repeated applications he was at last appointed honorary obstetric physician to the Rokus Hospital. The statistics of the institution show that during six years of his tenure of office, between 1851 and 1856, the rate of mortality was under 1 per cent.—viz., 0·85.

On the death of Professor Birley, Semmelweis was appointed to the chair of Midwifery at the University of Pesth. This promotion gave great satisfaction to his friends and the public. The condition of the maternity as to space and management was unsatisfactory; Semmelweis undertook to reorganise it. The surroundings of the clinique were most objectionable; he urged that a better building be provided. The anatomical dissecting-room on the ground floor, just under the midwifery wards, he insisted on closing at once, and made an urgent demand for a sufficient supply of bedding and linen. These and similar requests he never ceased to urge upon the authorities. He exercised the strictest discipline in demanding unconditional observance of antiseptic precautions. The many petty annoyances to which his official position subjected him, added to the utter disregard and misrepresentation of his views by some of the leading obstetricians on the Continent, proved particularly irksome and depressing to Semmelweis's sensitive nature. He eventually arrived at the conclusion that it would be a "crime" to remain silent any longer. "I am convinced," he says, "that since 1847 thousands of mothers and infants perished who might be living still, had I counteracted all the mischievous opinions that have been put forth with respect to puerperal fever. If now, after twelve years, we put the question, whether my teaching has fulfilled its object or not, the answer is very disheartening to me; it was not propounded sufficiently at first, but its substance was known, and one might have expected that to professional men, whose duty it is to save life, such indications would be sufficient in inducing them to lend serious consideration to the subject. This is a disease about which all speak with dismay, so when doubts were cleared away the principles should be unanimously recognised and adopted in practice. Yet in a great number of the lecture-rooms of to-day philippics are being delivered against my views, teaching the purely epidemic nature of the source of puerperal fever; from this it follows that successive crowds of septic inoculators are sent out on the public, and who can tell when we shall see the last midwife and country doctor cease to spread infection through ignorant malpractice?" These bitter words are sufficiently characteristic of the author's mental condition. When he began to write his great work "Die Ætiologie," he said in the preface: "Providence has chosen me as the exponent of the truths contained in this book. It is my bounden duty to stand up for them. I was obliged to give up the hope that the importance of the question would make it superfluous for me to fight for it. But I must not now take into account my inclinations; I have to consider only the lives of patients, who can take no part in our discussions, whether I be in the right and my opponents in the wrong." These words were written as if under a presentiment of a sad end which was soon to follow.

The great work "Die Ætiologie" began slowly, but by degrees its progress developed rapidly, one sheet followed another quickly, and the monograph, which was estimated at six sheets, swelled into a book.

The conclusions to which Semmelweis arrived may be summed up in the following:—In every case where puerperal fever exists the cause is absorption of decomposed animal matter poisoning the blood. It follows therefore that it is due, not to any specific miasma or malaria, but that it is a septicæmic and a pyæmic condition. As a rule, the cause of the disease is introduced from without—external infection; hence the origin of these fatal epidemics, which are preventable. In a few rare instances, when the membranes or placenta are in part retained and undergo decomposition, supposing that injury was inflicted on the parturient organs by instruments or otherwise, these may also serve to poison the blood. Such cases of self-contamination cannot, according to Semmelweis, be prevented. The rate of mortality from this cause he estimates at 1 per cent.

Some authors speak of topical inflammations during the puerperal state, and describe symptoms of circumscribed metritis, endometritis, metrophlebitis, oöphoritis, colpitis puerperalis, &c., as distinct affections not referable to blood poisoning. Semmelweis's experience does not admit the correctness of such theory, because he regards all such affections as proceeding from the same source, and as being preventable by the use of antiseptic measures, the milder affections being less severe manifestations of the same morbid process. So impressed was he of the paramount importance of the part played by septic poison, and of the necessity of using disinfectants, that he wrote as follows: "We beseech, therefore, all Governments to enact laws having for their object the saving of the lives of females, who are being decimated at present; to prevent this, the fatal virus should not be brought in contact with the yet unborn organisms—a calamity which, unhappily, is practised by those very hands whose duty it is to do all they can to preserve life." Semmelweis further proposes that the midwives and practitioners in attendance be bound down by a "special oath" faithfully to carry out the prescribed rules of treatment. Removal of maternity wards from insanitary surroundings, great care and gentleness in using instruments, scrupulous attention to general cleanliness, and frequent use of antiseptics in every form—these are the points the author insists upon. He refutes, sometimes with vehement invective, the opinions and arguments of his opponents, especially those of Scanzoni, Carl Braun, Zipfl, and Lumpe, some of whom he accuses of deliberate malevolence by systematically perverting his statements.

The book "Die Ætiologie" is a noble monument of the results of careful inquiry. The author expresses the hope that, as regards puerperal fever, his discoveries may not be regarded with less favour than were those of Jenner in another field. But it required time for sufficient notice being accorded to this work. Most of the data adduced by his opponents seemed unexplainable by the light of the new theory, and thus they endeavoured to stamp Semmelweis's labours as not worthy of serious consideration. Dr. Breisky especially criticised him with severity. To these strictures a telling answer was given by Dr. Markusovszky when he says: "The study of the etiology of puerperal fever is doubtless not yet cleared up; it would not have been so even then if the infection by decomposed organic matter had been generally accepted as the true cause. What Professor Semmelweis adduces is merely a preliminary definition of the origin of the disease, since its very elements—viz., pyæmia, the process of absorption (septicæmia), and the febrile manifestations—are matters for further investigation." Many other circumstances besides these kept Semmelweis in perpetual anxiety. His wards in the hospital were situated above those of the surgical patients. Against an arrangement so dangerous he never ceased to protest. In 1860 erysipelas and gangrene broke out in the wards below, and several deaths occurred in the maternity in consequence. This affected Semmelweis greatly, because he feared that this accidental death-rate would be cited as telling against his own treatment.

There remains but little to add, and what there is is a sad, if common, story. Semmelweis felt that he had grasped a great truth, which had been gradually evolved out of a long series of observations and much concentrated thought. It required far more robustness of intellect and character than Semmelweis possessed to front the opposition which his doctrines evoked, and to bear up against the delayed hopes

and disappointments that he had to encounter. To him their truth seemed so clear and unequivocal that opposition appeared to be nothing but the offspring of prejudice, almost vindictive in type. Semmelweis became introspective, desponding, irritable, and at last unreasonable. He had indomitable industry, a sagacious insight amounting almost to genius, but he had little of that fortitude which enables a man to *labour* and *to wait*.

Apart from his special study of puerperal fever, Semmelweis devoted attention to other branches of gynæcology. He performed ovariotomy, and wrote on uterine hæmorrhages, and on the treatment of fibrous tumours. But his mind was ever preoccupied by his favourite subject, to which he loved to allude in the course of his lectures on other matters. The long-continued stretch upon his mind left indelible marks on an impressionable temperament. Often, when speaking to his class, his excitement rose to such a degree as to cause alarm to those around him. A peculiarity of his conduct, the changeable temper, forgetfulness and carelessness, which characterised him of late, occasioned grave misgivings in the minds of his family and friends. The total break-down soon followed. In July, 1865, as he was about to make a report to the Committee of Professors concerning an appointment which was to be filled up, instead of doing this, in the presence of the assembly he took out of his pocket a piece of paper and read out a solemn oath which he proposed that every midwife and practitioner should be compelled to take. This unlooked-for incident produced consternation among his colleagues; there could be no longer any doubt as to the real state of his mind. All those present accompanied him home to his wife and family. After a few weeks the malady assumed a serious aspect, which rendered treatment in a private house impossible. Medical friends advised placing him in an asylum, and he was removed to Vienna on the 20th of July, 1865. Here he spent the few remaining weeks of his life, death releasing him from his sufferings on the 17th of August, in the forty-seventh year of his age. The proximate cause of his end was not cerebral disease, but that very affection—pyæmia—to the elucidation of which he had devoted the best years of his life. Before symptoms of mental derangement had set in, he performed an operation on a new-born infant, and inflicted a wound on his right hand; the injury was followed by a whitlow, and eventually blood-poisoning ensued. Semmelweis's remains were taken to their last resting-place from that very hospital in which he first made those observations the beneficent result of which will ever remain the glory of his name.

As time passes, the details of the struggle of bygone days are no longer seen in the same light as they were by those who took part in them: the judgment of posterity will be the result of calm reflection. Semmelweis, so full of sympathy for the sufferings of others, struggled unceasingly under unfavourable circumstances, till at last his body and mind succumbed under the heavy strain. He was laid in an untimely grave. But Semmelweis's sufferings were not purposeless. No better acknowledgment did he expect as the reward of his long sufferings than is expressed in the words of Dr. Dohrn in the last number of the *Zeitschrift zur Geburtshülfe und Gynækologie* (Band xii., Heft i., 1886), where he says, in speaking of statistics of puerperal fever: "We see that we in Germany have left those sad days far behind us, and that, as far as our public institutions (of maternity) are concerned, the severe judgment of Semmelweis is no longer applicable to them.....Nobody will deny Semmelweis's merit of having brought about an amelioration of former circumstances."

His biographer desires to place prominently on record the all-important fact that cadaveric infection alone, as some would have it understood, was not, in Semmelweis's opinion, the sole cause of puerperal fever; but, to quote Hebra's words of 1856, "infection with noxious discharges, emanating from living organisms, is likewise considered to be productive of childbed fever."

Nevern-square, South Kensington.

THE Duke of Connaught, who some time ago expressed his readiness to lay the memorial stone of the new circular ward hospital in course of construction at White Rock, Hastings, has written to the committee expressing his regret that, owing to his forthcoming departure for India, he will be unable to undertake the duty.

CASE OF

LABOUR FOLLOWED BY SUPPRESSION OF URINE.

BY J. T. WILLIAMS, M.R.C.S. ENG., L.R.C.P. ED.,
LATE ASSISTANT-SURGEON TO THE TREDEGAR IRONWORKS, MON.

ON Friday, March 26th, 1886, at 7 A.M., I was called to attend Mrs. G——, a primipara, whom I had never seen before. On my arrival the child was born dead, the labour having been very rapid at the last. The child was fully formed, and appeared to be about full time. The patient was just twenty-two, and seemed very quiet and easy—in fact, rather apathetic, as she evinced no sorrow at the death of the child. She was rather pasty in appearance, but not strikingly so. Having given the usual directions as to diet &c., I left her, promising to call again the same evening.

On my second visit I found her very comfortable, and to all appearance going on well. On inquiry, however, I found that she had vomited several times since the labour, and that she had passed no urine. The patient, however, complained of no pain over the bladder, and on percussion I could not make out any urine in it. I ordered hot fomentations over that region, and told the friends to let me know if she had any great pain, and I would come immediately and draw off the urine. I ordered her soda-water and diluents of that description.

March 27th.—I found that she had still voided no urine, and that there was no pain. She had vomited two or three times since my visit. I passed a catheter, and on its entrance into the bladder only about three drops came away. I then withdrew the instrument, passed a stilette through it, and reintroduced it, but no urine exuded. I now examined the patient very carefully. There was no history of renal disease in her or her family. She had never had scarlet fever. Her mother, who was the nurse, said that she had always been healthy and very lively. She had been married only four months. Temperature 99°; pulse 88; tongue dry, with yellowish fur on it; skin hot and dry. She was now more pasty in appearance than when I saw her first. The patient's manner was markedly quiet and uncomplaining. Her heart was weak and her lungs healthy. The lochia still continued, but were slight in quantity; the appetite was bad; the bowels not open; there was no anasarca or headache; pupils active. I ordered hot fomentations to the loins, soda-water and such-like diluents to drink, and an ounce of the following mixture to be taken every four hours: tincture of digitalis, two drachms; nitrate of potash, two drachms and a half; spirit of nitrous ether, three drachms; solution of acetate of ammonia, two drachms; water to eight ounces. I also gave her a drachm of compound jalap powder.

28th.—I called in the morning, and found the patient in much the same state, except that she had a very slight amount of dyspnœa. On examination I could find no signs at the base of the lungs of œdema or congestion. Her heart was the same as the day before. She had passed about four drops of urine. There was no pain in any part of the body. Her skin was becoming more and more sallow and pasty. On my visit in the afternoon, in company with another medical man, she was in the same condition as when I left her in the morning. We passed the catheter again, and drew off about half an ounce of urine. She was kept on the same mixture, and the soda-water &c. Diet was very light. The urine contained about one-sixth albumen, and was clear and pale. We could not take the specific gravity, as the quantity was not sufficient.

29th.—The bowels had been freely open twice since my last visit, but still no urine had been passed, and there was no pain over either the vesical or the lumbar region. The skin was still very dry. The only thing that the patient complained of was weakness. Temperature 99·1°; pulse 88. The tongue still had yellow fur on it. No dyspnœa at all. She had slept very well every night since her confinement. There was no anasarca, and the heart was working fairly well. I had warned the relatives of the gravity of the case, and had, in fact, told them that I thought she would not recover. It was hard to make them see that it was so serious, as the patient was to all appearance not in any great danger, so uncomplaining was she and with so few symptoms. In the evening there was no change. I passed the catheter and

drew off about one ounce and a half of urine, which was pale and clear, and on examination afterwards found it contained a considerable quantity of blood-colouring matter, with a very few hyaline casts and a large quantity of spheroidal epithelial cells like renal epithelium; sp. gr. 1020; albumen one-eighth. The bowels had not been open since I left in the morning. I gave her another drachm of the compound jalap powder, and kept her on the diluents and diuretic mixture, with the same light diet; hot fomentations to her loins as before. The milk had appeared in the breasts now.

30th.—It was now the fifth day after her confinement, and during that time the urine drawn off and passed was about two ounces. Her bowels had acted twice. This morning I found her weaker, and she had passed a very restless night. Her breathing was not at all impaired, and the heart worked fairly well. Temperature 99°; pulse 86. Tongue covered with the same yellow fur, but not quite so much. She had vomited once since the evening before. Lochia continued. Her appetite was very bad, and her mother found it difficult to get her to take anything. I proposed a consultation with another medical man, to which the relatives agreed. Accordingly at 6 P.M. I went with Dr. S——, and found that the patient had had an action of the bowels, once freely, since my last visit, but she had voided no urine, nor could we on percussion make out any in the bladder. She talked more cheerily than usual to-night, and seemed in better spirits; otherwise there was not the slightest change in her. Pulse 86; temperature 99·1°; tongue still covered with yellow fur. The same treatment was pursued, and we left about 7 P.M. At 9 P.M. I was called again to see her by her father, who told me that he thought his daughter had fainted. I thought perhaps she was comatose, so I took some pilocarpine with me, but on my arrival I found her dead. Her mother said that since we left the house she had appeared quite cheerful, that she had passed about a wineglassful of urine, and that her bowels had acted. She asked her mother to hold her in her arms, and it was while in this position that she turned on one side and died almost instantaneously. There was no convulsion of any sort. This is all I could get from the mother.

The appearance post mortem presented nothing very extraordinary. I could not obtain a necropsy, which I should much like to have done. I should be much obliged for any suggestions as to the pathology &c. of this as a complication of parturition. Ought any very prompt measures to have been taken at the onset of the disease, although so few symptoms presented themselves?

Widecombe, Devon.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF CONGENITAL DISLOCATION OF RADIUS.

By R. HEELIS, M.B.

J. H——, aged eight years, was brought to me by his mother, and I was asked to look at his left arm. At first the only abnormality I noticed was a swelling on the outer and anterior part of the forearm just below the elbow; but on a slight movement of the arm the head of the radius slipped out of place, and I was led to examine the case more closely, with the following result: The left radius is generally in its dislocated position, and if reduced any slight motion will throw it out of place again, especially pronation. In complete flexion the dislocation is reduced; it can easily be reduced by manipulation in any position of the forearm, as the joint is so loose and there is some lateral movement possible in the humero-ulnar articulation. The right radius is partially dislocated—that is to say, only about one-fifth of the circumference of the head rotates on the external condyle of the humerus, the rest projecting behind and to the outer side of the joint. This dislocation is irreducible—at any rate, unless considerable force were employed. The external humeral condyles on both sides appear to be unusually small, hence the difficulty of retaining the dislocated bone on the left side in position. The dislocation therefore is similar on both sides, being outward and backward. When the arms are extended there is a considerable projection on the outer and upper part of both forearms, produced partly by the outward dislocation and partly by the disproportionate development of the supinator longus. All the normal movements can be performed by both forearms, but pronation and supination, especially the latter, are very weak, and their place is usually taken by movements of flexion and extension. The patient seldom uses his right arm, which is less muscular than the left. The existence of some deformity has been noticed by the parents since his first year, and even from birth. There is no history of any accident to the boy or to the mother during gestation, or at delivery, which was normal. The boy is fairly well developed; his incisor teeth are very irregular, the two upper lateral or central ones being absent. He is loose-jointed. His manner is very restless, and has been since an attack of chorea three years ago, which chiefly affected his left arm and lasted one year. He is very backward in his education, scarcely knowing his alphabet. The patient's mother is healthy, and has had no miscarriages. The father is of strumous appearance and subject to styes. The brother, the only other child, has interstitial keratitis.

Remarks.—I believe the dislocations to be congenital, because they are symmetrical, and because they have been noticed almost since birth, and there is no history of accident to account for their appearance. The defective development of the teeth, bones, and joints, the backward intellect, and the attack of chorea seem to support the theory which refers congenital dislocations to lesions of the central nervous system.

Nottingham.

A CASE OF PARAMETRIC PHLEGMON FOLLOWING HYDATIDIFORM MOLE.

By G. HENRY BROWNE,

SURGEON, WAENAVON AND CLYDACH-MERTHYR COLLIERIES.

MRS. X——, aged thirty-two, a thin, pale woman, multipara, ceased menstruating on June 24th. Six weeks from this date flooding set in without assignable cause, which was checked by ergot and opium. A month later still the hæmorrhage recurred, and was again checked by the usual remedies. The patient had no further trouble till Oct. 4th, when an urgent message came for me to see her about 1 A.M. that morning. On arrival I found her suffering from very profuse hæmorrhage, the abdomen presenting the size of a seven months' pregnancy, but doughy on palpation, while per vaginam the os, soft and dilatable, was expanded to the size of a florin. From this condition of the parts I diagnosed hydatidiform mole, which diagnosis was subsequently confirmed by a portion coming away having the characteristic white-grape appearance. Ergot was given and a Barnes' bag used to avert hæmorrhage and dilate, severe pains almost immediately coming on. In about twenty minutes I removed the bag, when an enormous quantity of the cysts, nearly amounting to six pints, was expelled. The hæmorrhage at this time was extreme, and ergot was again resorted to with brandy, while with my left hand I grasped the uterus, which alternately contracted and relaxed, and with my right passed a few grains of iron-alum up to the os; immediate contraction then ensued and no further hæmorrhage occurred. From the great loss of blood the patient sank to the lowest ebb, being at one time almost pulseless, but rallied under the use of stimulants. When seen again at 11 A.M. her state was somewhat improved, pulse stronger, and temperature normal, and she was then ordered teaspoonful doses every hour of essence of beef (Lion brand), with a mixture containing ten minims of solution of extract of ergot, ammonia, and bark every four hours. Nothing untoward happened until eight days later on, when the patient was seized with a rigor soon after my morning visit, the lochia ceasing and the temperature rising to 101°, with a pulse of 104. She now complained for the first time of severe pain in the right groin, and on examination I found a large tumour, hard, inelastic, and dull to percussion, filling the whole of the right iliac fossa. I enjoined absolute rest in bed, treated the tumour locally with poultices and a liniment of iodide of potassium, belladonna, and glycerine, and gave her ten grains of quinine imme-

diately, with ammonia and bark every four hours. Next morning the temperature had fallen to 98·6°, but rose again at night to 101°, and in this manner continued hectic till October 23rd, the patient's strength during that period being supported by Richard's essence of beef, brandy and egg mixture, essence of malt, and beef-tea, besides taking ammonia and bark. Enemata of defibrinated blood were also used, from which great benefit was derived. The tumour up to this date had presented no perceptible alteration in size or hardness, but to my great surprise, on examining it, I found it diminished to less than half its original bulk, and this diminution continued without intermission—the patient's strength increasing in a proportionate degree—until at the end of three weeks (Nov. 14th) it was no longer palpable.

The points in this case which seem to me most worthy of interest are—the immediate action of the iron alum in arresting hæmorrhage, the sudden diminution in size of the phlegmon, and the great benefit obtained from enemata of defibrinated blood given daily during a fortnight when the anæmia was most marked.

Brynmawr, S. Wales.

RETRACTION OF THE PENIS.

By THOS. F. RAVEN, L.R.C.P., &c.

I SHOULD have published the following singular case some two years ago had I not feared that the strange details would be received with incredulity, but since a similar but more strongly marked example of the same condition has recently been recorded by Dr. Ivanoff in a Russian medical journal, I do not hesitate to bring my own experience forward.

A. B——, a healthy, steady, single man, aged twenty-seven years, shortly after he had gone to bed one night, felt a sensation of cold in the region of the penis. He was agitated to find that the organ, a fairly developed one, was rapidly shrinking, and was, he thought, finally retiring. He at once gave the alarm, and I was hastily summoned from my bed to attend him. I found him highly nervous and alarmed. The penis had almost disappeared, the glans being just perceptible under the pubic arch. The skin of the penis alone was visible, and looking as it does when the organ is buried in a hydrocele, or, in an extreme degree, as it does after death by drowning. I reassured him, and gave him some ammonia, and found next day that the natural state of things had returned. But he remained weak and nervous for some days. He could give no explanation of the occurrence, and the unnatural condition has never returned. The circumstances of this case were not of so distressful a character as those related by Dr. Ivanoff. In his case the penis had bodily disappeared, and was recaptured only after prolonged manipulation. Even then the patient seems to have distrusted its tendency to remain in its natural position, for he had tied a string around it above the glans, in order that it should not again escape him. In this instance, too, the result was satisfactory, but the tendency to retraction was not finally subdued until the patient had been six days under treatment. He was a peasant, aged twenty-three, a married man with a family.

Broadstairs.

MEDICAL STUDENTS IN SWISS UNIVERSITIES.—The number of medical students in Switzerland appears to be increasing. During the present summer session the total is 675, including 81 women, who are admitted in Berne, Geneva, Zurich, and the preparatory school of Lausanne, but not in Basle. In Berne there are no less than 40 female students; some of the assistants' posts are filled by women. It is remarked that their exercises, or degree theses, are usually selected from theoretical subjects—such as anatomy, physiology, pathological anatomy, and pharmacology,—rather than from practical medicine and surgery. The increase in the number of students is due almost entirely to an accession from Switzerland itself, the number of foreigners (192) being much the same as in former years. Of the 81 female students, only 10 are of Swiss nationality.

AT an inquest held recently on the body of a lunatic who had committed suicide by leaping into a deep pond in the grounds of the County Down Asylum, Downpatrick, the jury very wisely recommended that a wall should be built round the pond.

LONDON HOSPITAL.

TWO CASES OF OPERATION BY SÉDILLOT'S METHOD FOR REMOVAL OF EPITHELIOMA OF THE TONGUE; RECOVERY IN BOTH.

(Under the care of Mr. WALTER RIVINGTON.)

DURING the last few months we have given examples of the removal of malignant growths from the tongue by various methods, and in the following two cases will be found a description of the removal of such by what is known as Sédillot's operation. It is not necessary to add to the description of the operation, nor to say more as to the class of cases in which it is applicable, these being chiefly those in which the floor of the mouth is involved as well as the tongue. If non-union after division of the jaw in the middle line were a frequent occurrence, it would be a serious bar to the performance of this operation; but this is not common, and probably the union is only delayed in these cases.

CASE I.—Jas. W. P——, aged sixty, printer, was admitted on Dec. 7th, 1885. He noticed a small lump in his tongue early in October. At first he did not pay any attention to it, but finding that it did not disperse, he consulted a doctor, who advised him to come to the hospital. For some months before observing the lump he suffered from pain referred to the temporal region. The only history of cancer in the family consisted in the fact that an aunt of his had cancer of the breast at sixty years of age; she was operated on and lived to seventy without return of the disease. The patient had smoked continuously for twenty years, using a clay pipe, most frequently on the left side, occasionally on the right or in the centre of the mouth. On inspection, a hard irregular ulcer was seen on the left side of the tongue extending into the floor of the mouth. The surrounding hardness extended beneath the mucous membrane as far as the middle line of the tongue, invaded the floor of the mouth, and reached outwards to the inferior maxilla. There were some old decayed teeth opposite the ulcerated portion of the growth, and the part was tender and bled readily on being touched. No enlarged glands could be detected. There was no history of syphilis or addiction to alcohol. Owing to the invasion of the floor of the mouth and the close proximity of the growth to the jaw, it was decided to perform Sédillot's operation by division of the inferior maxilla. The operation was performed on Dec. 16th. An incision was made in the middle line from the border of the lower lip to the hyoid bone, the jaw cleared slightly, drilled with two sets of holes, sawn through vertically, and the halves drawn asunder. The genio-hyoglossi and the mucous membrane were divided, and the left sublingual gland removed. After clearing the tongue as far as the base, a wire-rope écraseur was applied close to the epiglottis, the division of the tongue occupying twenty minutes. A ligature was put through the stump that was left, the jaw wired, and the soft parts stitched. A drainage-tube was inserted and brought out below the jaw. Two or three small arteries were tied, but there was no bleeding from either lingual or coronaries. Not more than half an ounce of blood was lost during the whole operation or afterwards. Subsequently the mouth was thickly powdered with iodoform, and the patient fed by nutrient enemata and suppositories. The mouth was carefully sponged out with an antiseptic solution every half-hour through the day. The wound in the soft parts healed by first intention. The jaw did not show any signs of union for some time, and the wires were allowed to remain. Before he left the hospital the union was rather firmer, but the halves were readily movable. The temperature rose to 100° for three days after the operation, but afterwards continued normal. He was discharged and went into the country on March 15th, 1886, quite well, the union still

being fibrous and the isthmus faucium contracted. He was seen early in June; the jaw was then quite firm. A lump had appeared on the left side of the neck underneath the sterno-mastoid. The mouth was free from recurrence of the growth.

CASE 2.—Henry H——, aged sixty-one, cab-driver, was admitted on Feb. 23rd, 1886. The patient's family is healthy and strong. He himself had syphilis forty-five years back, and a year ago some kind of skin disease; otherwise he had always been strong and healthy. Four months ago he noticed that his tongue was sore and painful on the left side; his teeth were very "scraggy" on that side. He was a constant smoker, but always held the pipe in the middle of his mouth. He gave up smoking, but the ulceration spread and became so painful that he could neither eat nor drink with comfort. He had been losing weight all the time. On admission the whole of the left side of the tongue from tip to root was ulcerated, the base of the ulcer being indurated, the edges nodular and everted, and the surface covered with a yellow coating. There was an enlarged submaxillary gland on the left side of the neck. As the growth extended deeply beneath the tongue and beyond its limits, Sédillot's operation was selected, and performed on March 3rd, precisely in the same way as in the previous case. After the removal of the tongue with the écraseur, a portion of growth was found reaching back on the left side beyond the point of section, and as far as the anterior pillar of the fauces. This had to be dissected out. Paquelin's cautery was used, but the lingual artery was not sealed, bled freely, and was secured by a ligature. There was more hæmorrhage than in the previous case, and the operation lasted much longer, as he took the anæsthetic badly. The floor of the mouth was powdered with iodoform, and the external wound dressed with iodoform and wood-wool pads. After the operation the patient was fed with nutrient enemata for a few days; the mouth was washed out every half-hour with Condy's fluid, and kept powdered with iodoform. On the third and following days he was fed by the œsophageal tube, a quart of a mixture of beef-tea and milk being injected into the stomach night and morning. All stitches were removed. Several attempts were made to get the patient to swallow his food, but it was impossible, as it collected in the great pit in the floor of the mouth, and ran out of the drainage-tube. Accordingly the tube was removed, and the sinus touched with nitrate of silver on March 16th. He had fits of great restlessness, getting out of bed and throwing the chairs about. He repeatedly asked for his clothes, and made up his bundle to go home. He was very dirty in his habits. Nevertheless he made a good recovery, and in a few weeks was discharged well. The union between the halves of the jaw was only fibrous when he left the hospital, as in the previous case. He has not been seen since that time.

WEST LONDON HOSPITAL.

CASE OF ENTERIC FEVER, FATAL ON ABOUT THE SEVENTIETH DAY FROM PERFORATION; SYMPTOMS OF PERITONITIS EXISTING FIFTY DAYS; NECROPSY; REMARKS.

(Under the care of Dr. DONALD W. CHARLES HOOD.)

WE are indebted for the following notes to Dr. Harper and Mr. Taylor.

A. R——, general servant, applied at the out-patient room of Dr. Ball on the afternoon of April 27th, 1886. The patient complained of pain over the region of the abdomen. Dr. Ball, finding much swelling of the abdomen and severe constitutional disturbance, ordered her admission. He diagnosed enteric fever with probable perforation.

On admission the patient was noted as being a fair, delicate-looking girl, aged nineteen. Her history, as far as it could be ascertained, was as follows: She had been feeling very poorly for about three weeks, though able to do her work. She had lost her appetite, and had had attacks of vomiting and griping abdominal pains. Within the last day or so these pains had much increased, and she noticed that her abdomen was swollen; and in consequence she sought advice at the hospital. No exact report with regard to the state of the bowels could be obtained; for at one time the patient stated that they had been confined, and at another that she had suffered from diarrhœa. The girl was too ill to give a satisfactory history, and none could be given by her friends. The abdomen was much distended; it was dull in the lower flanks, and a slight thrill could be felt on making gentle percussion; the distension obliterated both iliac and hypochondriac depressions. The pulse was 96, temperature 101·4°, and respiration 24. The patient was very deaf and listless. She lay on her back with her legs drawn up. She did not appear to suffer from pain, and passed most of her time in sleep, taking her nourishment without difficulty. The tongue was much coated and dry.

The following day the symptoms were increased in severity, the abdomen being more distended and tympanitic, and the presence of fluid being easily demonstrated. The pulse was 106 and the temperature 103°. The bowels acted naturally. For the next few days there was but little change, but on May 8th, being eleven days after admission, there was a decided remission in the severity of the attack; the abdomen became less tense and swollen, the thrill was completely lost, and the temperature and pulse both fell; the patient was bright and cheerful in manner, lost her deafness, asked for books, took interest in her surroundings, lay comfortably on her side, and appeared to be better in every way. The remission in the intensity of the symptoms continued for about eight days, but during this time the irregularity in her temperature gave cause for much anxiety; on May 13th it was noted as being 99°, but it rose again the following day and presented an irregular zigzag course until death. From May 13th till June 8th the symptoms presented no striking variation; the patient appeared fairly comfortable, and persisted in saying she felt much better. The bowels acted naturally; there was little or no abdominal pain; the distension was much less, though still evident. On the evening of June 7th (forty days after admission) the temperature suddenly rose to 104·8°, the patient had an attack of vomiting, and on the following morning complained of severe pain over the lower part of the abdomen. Swelling and tympanites quickly followed. The vomiting was the most distressing symptom. The temperature gradually fell until the morning of the 11th, when it reached 99°; it rose again on that evening to 103°, and did not again fall below 100°. The patient remained in this state for the following six days, sinking from exhaustion on June 13th, the forty-seventh day after her admission, and, as far as could be judged, about the seventieth of her fever.

At the post-mortem examination made by Mr. Percy Dunn, the abdominal cavity was found full of purulent fluid containing fæcal matter, the fetor of which was extreme. There was general thickening of the peritoneum, and adhesion of neighbouring organs. Scattered over the intestines were recent, as well as old, signs of peritonitis. A large circumscribed collection of pus was found lying between the liver and the diaphragm. On examining the lower portion of the ileum, three of Peyer's patches showed unmistakable signs of old typhous process, the patches being indurated and thickened, and one of them was distinctly cicatrised. Close to the ileo-cæcal valve was an irregularly shaped shaggy perforation, the perforated portion abutting on to a Peyer's patch which had still an ulcerating surface. For three or four inches at the lower part of the ileum the bowel was found closely adherent to a corresponding loop of small intestine. Their adjacent coats were firmly adherent, and so closely agglutinated together as to present the appearance of a double cylinder without any apparent intercommunication.

Remarks by Dr. HOOD.—The condition of the patient on admission was such as to warrant the diagnosis of enteric fever with perforation. As week after week passed by, I felt some diffidence in adhering to this diagnosis, and I felt more disposed to look upon the case as one of some local trouble complicating the peritoneal cavity. The post-mortem cleared up the matter, and demonstrated conclusively that the first attack of abdominal pain and peritonitis had been caused by perforation of a typhoid ulcer, and I conclude it was at this period of the illness that the inflammatory action had been started which eventually led to adhesion between the two adjacent layers of ileum. The inflammatory mischief slowly smouldered on day after day, until a second perforation set up fatal peritonitis.

SALFORD ROYAL HOSPITAL.

CASE OF UNUSUALLY LARGE CALCULUS REMOVED FROM A GIRL PER URETHRAM.

(Under the care of Mr. ANDREW BOUTFLOWER.)

H. H—— aged twenty-one, was admitted on Jan. 11th, 1886. She complained of total incontinence of urine, accompanied with great pain. On examination, a very large calculus was felt through the vaginal wall of the

bladder. At the age of ten she suffered from morbus coxæ; abscesses formed in the groin and gluteal region, with extensive sinuses, frequently discharging small pieces of bone, which had for a long while been completely healed. Since that time she had been perfectly well, with the exception that twelve months ago she menstruated irregularly, and had to get up frequently at night to urinate, which was always accompanied with difficulty and a bearing-down pain. This condition gradually became worse; the urine became white and thick, and had to be passed every hour; latterly complete incontinence had supervened.

When admitted she was much emaciated; the urine was alkaline, with heavy phosphatic deposit. An operation was performed on Jan. 16th. After rapid dilatation of the urethra with the fingers, the intention was to introduce a lithotrite and crush, but this was found difficult to accomplish. The bladder was tightly contracted round the stone, and injection of the bladder was useless. Owing to this contracted condition it was found impossible to grasp the stone with a lithotrite without including mucous membrane. A pair of lithotomy forceps was therefore introduced, and with gentle traction, but not without considerable difficulty, the stone was extracted, the procedure causing some laceration of the urethra. The stone weighs 2½ oz.; it measures 2¾ in. in length by 1¾ in. in width, and is nearly 4 in. in circumference.

For the first ten days after the operation the patient progressed most favourably; after this some septicæmic symptoms developed, but these have passed away, and she is now quite well. Some degree of incontinence still exists, but it is hoped that this discomfort may gradually subside.

Remarks by Mr. BOUTFLOWER.—It is always easy to be wise after the event, but I have no hesitation in saying that if such an unusual case ever came under my care again, I should certainly remove the calculus either by the supra-pubic or vaginal lithotomy.[1]

Medical Societies.

ACADEMY OF MEDICINE IN IRELAND.

Pyo-pneumothorax.—Displacement of the Heart.—Acute Pericarditis.—Horse-shoe Kidney.

A MEETING of the Pathological Section was held on May 14th.

Dr. WALLACE BRATTY exhibited the lungs from a case of Left Pyo-pneumothorax secondary to Phthisis. The patient, a young man aged twenty, had been in the Adelaide Hospital last July for a few days with symptoms of pulmonary phthisis and stethoscopic evidence of that disease in the upper lobes of both lungs. On Oct. 24th he was seized, when coughing, with a severe pain below the left clavicle, causing a sensation as though his left lung was breaking in two. He was admitted into hospital on Oct. 27th. On admission, the characteristic signs of left pneumothorax were present, and after a few weeks fluid was effused into the lower part of the pleural cavity, as was evidenced by percussion dulness at the left base and succussion splash. There were physical signs of excavation in the upper lobe of the right lung. The patient lived six months after the occurrence of the pneumothorax. On post-mortem examination, the left half of the diaphragm was found depressed, convex downwards, and extending an inch and a half below the lower border of the left costal arch. It had doubled the left lobe of the liver upon itself. The right half of the diaphragm was in its normal position. Gas escaped from the left pleural cavity on its being opened; that cavity contained about five pints of odourless pus. The pleura was much thickened. The left lung was carnified, very small, and pressed up against its root, except at the upper part anteriorly, where adhesions bound it to the chest wall. At the inner surface in its upper part a circular opening or ulcer was found, in diameter about the size of a sixpence, shallow in its posterior half, where there was a minute pin-hole perforation; in its anterior half it was about a quarter of an inch deep, and subdivided by bands of lung tissue. The upper lobe of the right lung presented numerous cavities, the lung tissue between the cavities being consolidated. The only healthy surface the patient had was that of the lower lobe of the right lung.—Dr. FINNY said he saw the patient twice through the kindness of the authorities of the Adelaide Hospital. The first time was early in December, and the physical signs of pyo-pneumothorax were then very well marked on the left side, but he did not remember seeing any marked signs of the disease on the right side.—Dr. HENRY KENNEDY said that in the majority of cases this disease occurred on the left side, and such had been his experience. Except in two cases, he had never failed at a post-mortem to find out where the opening was. It generally occurred at the base of the upper lobe, immediately under where the attachment of the lobe ceased and false adhesions began. They knew that adhesions took place in this disease long before the occurrence of the event which caused the pneumothorax; and, according to his experience, it was immediately below where these adhesions ceased, and at the base of the upper lobe, that the opening might be found. As to the duration of the disease, in the present case, it was unquestionably unusual that it should have lasted so long.—Dr. BEATTY, in reply, said perhaps he had been wrong in not tapping the left side of the chest; but when the patient first came to the hospital there was no fluid in the pleural cavity. Afterwards a small quantity of fluid was effused; and as there was marked evidence of the upper part of the right lung being diseased, he thought that, both lungs being diseased, tapping would hardly prolong the patient's life.

Dr. C. J. NIXON communicated a case of Displacement of the Heart in Aortic Patency, and exhibited the specimen. It was the heart of a man of about sixty years of age, who was admitted into the Mater Misericordiæ Hospital with the physical signs of aortic patency. On examining his chest with the stethoscope, an extremely well-marked hissing murmur, diastolic—or rather post-diastolic—in time, and having its maximal point of intensity at a line connecting the two fifth costal cartilages—in other words, a little above the base of the ensiform cartilage on the left side—was heard. That murmur was not audible at the apex of the heart. Travelling upwards towards the aortic area the murmur ceased, and over that area, and above the systolic murmur, was heard a well-pronounced aortic sound. In the carotid arteries a loud, hoarse, systolic murmur, which was followed by a distinctly marked aortic second sound, was noted. He pointed out to Dr. MacSwiney the peculiarity in the physical signs, which was that they had a very well-marked murmur of aortic regurgitation, having its maximal intensity at the base of the ensiform cartilage at the left side; and yet over the area proper there was a distinctly marked aortic second sound, and the aortic second sound was heard in the carotid arteries. He pointed out that it rarely happened that the aortic murmur of regurgitation was not a substitution sound—that it was only in exceptional cases that the murmur of regurgitation and the aortic second sound were both heard well marked. The difficulty in such cases was to determine whether the sound was an aortic or a pulmonic sound. The aortic second sound was most clearly pronounced in the carotid arteries. With regard to the explanations which were given of the contemporaneous occurrence of this sound and of the murmur of regurgitation, one was the theory of Dr. Hayden, that in cases of commencing aortic incompetency, the aortic segments might be sufficiently sound to produce by their tension a clearly defined second sound, which yet might be represented by a murmur following that second sound. The murmur in the present case was clearly post-diastolic, and seemed to correspond with what was heard in the cases of aortic patency described by Gairdner, where the sternum acted as a sounding-board, and conveyed the murmur of aortic regurgitation downwards, so that it was best heard over the base of the ensiform cartilage. At the apex of the heart the first sound was feebly pronounced, and the aortic diastolic murmur was heard indistinctly. The impulse beat of the heart was about an inch to the left side of the nipple, in the fifth intercostal space. The apex beat of the heart, in place of being displaced downwards, was slightly upwards, but considerably to the left of the nipple-line. There was in the epigastrium a par-epigastric impulse of very marked intensity. The course of the case was rather rapid, and the man, on making some slight exertion in bed, fell back and died. The heart was found to be greatly enlarged. The walls of the left ventricle were considerably hypertrophied, and its cavity dilated. The

[1] These notes were read, and the calculus shown, before the Manchester Medical Society on March 3rd, 1886.

hypertrophy of the musculi papillares was more or less in correspondence with the hypertrophy of the walls of the ventricle itself. The aortic valve segments did not appear to be very much altered by disease. They were smooth on the surface and fairly competent, but there was at certain points enormous thickening of the valvular attachments, and the thickening was almost cartilaginous in density. On applying the usual water-test, the valves were found to be incompetent, but not to any marked extent. The right ventricle and the right side of the heart generally were considerably dilated, and the walls of the left ventricle were hypertrophied. The first point in connexion with the case was that the pathological appearances explained the physical signs. The aortic valve flaps were in themselves texurally sound enough to produce by their tension a clear and well-defined aortic second sound. That was the condition that existed in the case. The thickening of the attachments of the valve flaps to the aortic zone produced a certain amount of contraction of the orifice, giving rise to the systolic murmur; and the slight amount of incompetency of the valves led to the murmur of regurgitation. The next point of interest was the position of the apex beat of the heart. Many years ago he heard Sir Dominic Corrigan lecture on the alteration in the position of the heart which occurred in the disease with which his name was associated—namely, aortic patency. He held that there were two displacements occurring in the disease. One took place in its earlier stages, resulting from the constant regurgitation of blood from the aorta to the ventricle, and the subsequent changes that ensued upon the incapacity of the ventricle, and was a displacement of the heart downwards. Afterwards, according to Corrigan, the displacement of the heart downwards was arrested by the diaphragm, and the heart underwent a rotation by which its apex was twisted upwards towards the left side. He did not think this explanation true. In the first stages of the disease they had the usual displacement of the apex beat which followed the hypertrophied and dilated left ventricle—that was, a displacement of the apex of the heart downwards and slightly to the left side. But after that an enormous distension of the ventricle took place, and then they had certain influences produced by that condition of the ventricle on the circulation through the left auricle and through the right side of the heart. The final result would be a great distension of the right side of the heart—first a dilatation of the auricle and then a dilatation and subsequent hypertrophy of the left ventricle. They should bear in mind the exact position of the left auricle in relation to the right lung—that the right auricle rested on the middle lobe of the right lung; and, according to Hilton, they might regard the middle lobe of the right lung as a sort of anatomical wedge, which afforded a very complete support to a portion of the heart which was very distensible—namely, the right auricle. The changes that occurred in aortic patency caused very great distension of the right auricle; and if that right auricle rested against a portion of the lung not likely to expand before it or make way for it, the result was that with the increasing distension of the heart the right side of the heart would generally tend to assume a more horizontal position, and its apex would be displaced to the left side. This, he thought, was a better explanation of what occurred than that given by Sir D. Corrigan. Another important point in connexion with that view was that in those cases in which they had great distension of the right side of the heart they would also have a great amount of turgescence and distension of the liver. The liver would then become like an erectile organ, and its pressure upwards against the diaphragm would more or less impede any downward pressure upon it; so that a lateral movement of the heart towards the left would be favoured.—Dr. FINNY asked how Dr. Nixon explained the very sudden death of the patient where the regurgitation was of such a very slight character, according to his own showing. The valves were evidently of sufficient tone to produce a good second sound. Sudden death in cases of aortic patency was a rare phenomenon. What proof was there in this case that the right side of the heart was at all affected, the mitral valve being competent? He could not see how Dr. Nixon's hypothesis explained the displacement. —The PRESIDENT said he was disposed to think that Dr. Nixon did not give quite its full value to the fixity of the diaphragm in his explanation of the phenomenon of the changing direction of the heart that he sought to illustrate. That change in direction in advanced cases of aortic disease had been long recognised, and he thought that, even on Dr. Nixon's own interpretation of the descent of the right side of the heart, in virtue of the enlargement of the right side—which he could quite understand independently of obstruction of the mitral valve,—it was necessary that the fixity of the diaphragm should be introduced as a factor in explaining that the whole heart did not go down with the right side in these cases, as they knew it did in other cases. Certain points would lead them to believe that Sir Dominic Corrigan was right in attaching a great deal of importance in cases of this kind, as well as of pericardial effusion, to the fixity of the diaphragm. Modern anatomical writers had described certain ligamentous structures as tending to attach the diaphragm upwards towards the upper outlet of the thorax in a much more recognised manner than had been in former times observed; and the observations of Virchow on the fixity of the diaphragm as one of the chief elements regulating the position of the abdominal and other viscera led him (the President) to attach more importance to it than Dr. Nixon seemed to have allowed.—Dr. NIXON, in reply, said the explanation of the patient's sudden death was to be found altogether in the condition of the myocardium, which he had not time to examine, but he took it for granted that it was in a state of fatty change. He found the left ventricle full of currant-jelly matter; and as regarded the sudden death, the case seemed one of paralysis of the heart in diastole. As to the explanation of aortic patency as following changes on the right side, Dr. Finny knew as well as he did that there were cases of aortic patency in which there was not displacement of the apex of the heart upwards to the left side. There were displacements of the apex which were found in dilatation and hypertrophy of the left ventricle, and which were distinctly downwards and to the left side; but when they found that the displacement to the left side was carried upwards and in a horizontal direction, they must admit the existence of another factor in producing that change. The only factor that he knew would be the subsequent changes in the right side of the heart following the changes in the left. It was not necessary, in cases of aortic patency, in explaining a dilated condition of the right side of the heart to assume mitral inadequacy. If, in a case of aortic patency, the left ventricle was filled from two sources in place of one, obviously there was from that circumstance an impediment to the free and thorough emptying of the left auricle, which must subsequently lead to the distension of that chamber and to the subsequent implication of the chambers on the right side of the heart. And they were not, in such a case, to look for any changes in the curtains of the mitral valve to explain mitral regurgitation.

Dr. FINNY exhibited a specimen, two days old, of Acute Pericarditis. It was taken from a man fifty-two years of age, addicted to alcoholism, which had caused him to lose a great many good positions. He came into hospital almost in a state of collapse, and was pulseless, cyanotic without œdema of the legs. Neither of his heart sounds could be felt, and scarcely heard; and it was only with great difficulty, and after free stimulation, that his pulse could be detected at the wrists. In this condition he remained for some days, and then died. The physical signs were dulness over the præcordial region, resembling closely, but not accurately, that in præcordial distension; while the absence of sounds of the heart outside the præcordial region, and absence of any præcordial impulse anywhere, made the case one of no little difficulty to interpret. The specimen was an example of well-marked acute pericarditis, in which adhesions were forming from one surface to the other.

Dr. NIXON exhibited a Kidney from the patient on whose remains he had made the post-mortem in the case of aortic patency. He found great difficulty in removing it, and then discovered it to be a beautiful example of a horseshoe kidney. The lower ends of the two kidneys were connected by a band of renal substance passing between the vertebræ and the abdominal artery, and by means of which the two kidneys were rendered perfectly continuous. The ureters passed down in front of the band, which was exceptional, their usual course, according to Bartels, being behind the transverse band.

SIR GEORGE H. PORTER, surgeon-in-ordinary to the Queen in Ireland, has been appointed a governor of the Richmond District Lunatic Asylum; and Mr. Mapother, surgeon-in-ordinary to his Excellency, a governor of the House of Industry Hospitals, Dublin.

The International Encyclopædia of Surgery. A Systematic Treatise on the Theory and Practice of Surgery by Authors of various Nations. Edited by JOHN ASHHURST, jun., M.D., Professor of Clinical Surgery in the University of Pennsylvania. Illustrated with chromo-lithographs and wood-cuts. In Six Volumes. Vol. VI. London: Macmillan and Co.

WE are glad to congratulate Dr. John Ashhurst on the completion of the sixth and last volume of the International Encyclopædia of Surgery, a work that represents in a very satisfactory manner the existing condition of that branch of medical science. There are both advantages and disadvantages in the production of a composite work of this kind; in some respects it contrasts unfavourably and in others favourably with a treatise written by a single hand. In the latter case the author, always supposing him to be well fitted for his work, writes with a breadth of view resulting from his wide knowledge, that enables him to seize upon the more salient points and bring them into strong relief; he can preserve the perspective of the subject more perfectly, avoid useless repetitions, and weld all into a harmonious whole. On the other hand, the advance of surgery has been of late years so rapid and great, that it has become almost impossible for any single practitioner to acquire such familiarity in every branch as to constitute him an authority on all, and in many he must necessarily be entirely dependent on the information contained in books, and find it difficult or impossible to distinguish the trustworthy points in the history or treatment of disease or injury from the specious and false. This difficulty is entirely overcome when each affection is placed in the hands of a writer who has given special attention to the subject. We may then expect that each article shall not only supply a thoroughly satisfactory account of the subject with which it deals, but that it shall be enriched with the author's experience, and that it shall contain much of that floating knowledge which has not yet found its way into books, but forms so important a part of the instruction that is given and received by the masters in a craft.

The Encyclopædia before us, the successive instalments of which we have noticed as they appeared, forms six large—perhaps a trifle too large—and heavy volumes, averaging 950 pages each; and Dr. Ashhurst has secured an excellent staff of contributors, seventy-one in number, forty-six of whom are American, thirteen English, and the rest French or German. It is a little more than four years only since the first volume was issued, and the rapidity of publication has therefore been very creditable to Dr. Ashhurst's energy. This period, short as it is, has been sufficient to include the deaths of six American contributors and one English—namely, Professors Gross, Van Buren, Otis, Bell, Lidell, Hodgen, Hodge, Hunter, Post, Sims, and quite recently Royes Bell. The present volume concludes the consideration of the injuries and diseases of the various regions of the body, and supplies certain articles which were necessarily omitted from previous volumes owing to the inability of their authors to complete them in time for insertion in their appropriate places. The chief of these are: Injuries and Diseases of the Œsophagus, by Professor Solis-Cohen of Philadelphia; Intestinal Obstruction, by the Editor; Injuries and Diseases of the Rectum, by Mr. Allingham; Urinary Calculus, by Professor Keyes; Crushing Operation for Stone, by Professor Hingston; Surgery of the Bladder and Prostate, by Mr. Reginald Harrison; Surgery of Male Urethra, by Professor Duplay of Paris; Surgery of Male Generative Organs, by Mr. Royes Bell; Injuries and Diseases of the Female Organs of Generation, by Professor Parvin; Cæsarean Section and Allied Operations, by Dr. R. P. Harris; Ovarian and Uterine Tumours, by Dr. Charles Lee. Ollier, Vincent, and Poucet of Lyons contribute three articles on Diseases of the Bones; and one on the Treatment of Deformities is written by Mr. F. R. Fisher. An excellent memoir is appended by Dr. Cowles on the Construction and Organisation of Hospitals. Clements gives a good account of the preparations to be made by surgeons in time of war in entering upon field duty, with a description of the modern system of ambulance service; and Dr. George Fisher gives a history of surgery. The work closes with a good general index. It is impossible to notice all the articles contained in this volume, especially as many of them are of great length; but we may select one which seems to us exceptionally good—namely, that on Urinary Calculus, by E. L. Keyes, the Professor of Genito-Urinary Surgery in the Bellevue Hospital Medical College of New York.

Dr. Keyes begins with a historical introduction, in which he points out that the first appearance of calculous disease cannot be determined, but an authentic record of stone exists in a medical treatise named "Sucruta," a Hindoo work, believed by some to antedate the Hippocratic collection. In this work, which was published in Sanscrit at Calcutta in 1835, a very fair description of cutting for stone "upon the gripe" is given—the method now commonly known as the method of Celsus. The Chinese are believed to have been acquainted with stone long before the modern era. Dr. Keyes defines a stone to be a body presenting a laminated structure under the microscope, while separate crystals or agglomerations of crystals he terms gravel. In the formation of most calculi he believes inflammation of the mucous membrane of the urinary tract to be an etiological factor. He brings evidence to show that the view of Cadge and Reginald Harrison, that hardness of drinking-water is a cause of calculi, is incorrect. Uric acid calculus is, curiously, uncommon in Finland, the University Hospital case-books showing only one Finlander with uric acid stone during a period of forty-four years. He supplies much interesting information not elsewhere accessible in regard to the occurrence of stone in other nations. The causes of stone formation are then discussed, and much weight is laid upon Dr. Ord's observations on the importance of the colloids. The influence of sex, race, climate, social condition, constitution, and heredity are considered. Dr. Keyes proposes the following classification: (1) Primary stone, the urinary mucous tract being healthy when the stone forms, which includes uric acid and the urates, oxalate of lime, cystine, xanthine, carbonate, and crystalline phosphate of lime and indigo; and (2) secondary or symptomatic stone, the mucous membrane being in a catarrhal state, including urate of ammonia, triple phosphate, amorphous phosphate of lime, fusible calculus, and urostealith. The structure of stones, their rate of growth and general characters, are then described. Several examples of the large number that may occur are recorded, one of the most remarkable being that of Chief Justice Marshall, of the Supreme Court of the United States, from whose bladder Dr. Physic extracted over a thousand stones. The spontaneous fracture of calculi is discussed, and Dr. Ord's conclusions given. A section is devoted to the consideration of the several materials of which calculi are formed, and a short but good section to the chemical analysis of stone. The pathological results of stone in the kidney, bladder, and urethra are next considered; and then follow sections on the symptoms of stone in the bladder, its diagnosis, and the several methods of treatment, including the preventive, the electrolytic, the solvent, the palliative, and finally the radical, which includes lithotomy, lithotrity, and litholapaxy. The statistics of these various operations are extraordinarily well given, and are very suggestive. The author strongly advocates litholapaxy, and also insists

on the preparation of the patient for the operation. The varied forms of lithotrite instruments are figured, including those of Thompson, Bigelow, Otis, and Guyon. The whole article is written in excellent style, and is very instructive to even the most experienced surgeon. There is a short additional paper by Hingston on Lithotrity.

We must not conclude without again congratulating Dr. Ashhurst on the completion of his Encyclopædia. The editing of such a work is, as we are well aware, a most laborious undertaking, but we think that he has every reason to be satisfied with the manner in which his collaborateurs have done their work. Many of the articles will become standard treatises on the subjects of which they treat, and all show care and judgment in their preparation. The work should be in the hands of every surgeon.

Surgical Operation Chart. By L. HEIDENSTAL ORMSBY, M.D., F.R.C.S., Surgeon to the Meath Hospital and County Dublin Infirmary, &c. London: Baillière, Tindall, and Cox. Dublin: Fannin and Co.

THIS chart, which measures about three feet by two, has been arranged and tabulated by the author in six sections. It shows at a glance the instruments, appliances, and dressings required for the performance of all the major and minor operations of surgery. Section I. contains an account of the preliminary arrangements to be made and requisites to be provided in the operating room or theatre. Section II. supplies directions for the sick room or ward after operations. Sections III., IV., and V. comprise lists of instruments and appliances required for operations about the head and neck, the trunk, and the extremities respectively; whilst Section VI. pertains to "varied and special operations." As stated by Dr. Ormsby, the chart is "designed for the use of house-surgeons, junior practitioners, and surgical dressers." It would undoubtedly be an acquisition to the operating theatre of every hospital, as it would serve to prevent those delays which so frequently occur, and which are so annoying to the surgeon during the performance of operations—delays consequent on the oversight of officials whose duty it is "to have everything ready." It is a valuable aid as a reminder to surgeons preparing for operations in private. We unhesitatingly commend it to the profession.

ARMY MEDICAL SCHOOL AT NETLEY.

THE summer session of the Army Medical School was brought to a close at the Royal Victoria Hospital, Netley, on Friday, July 30th. The duty of handing the awards to the successful surgeons on probation had been undertaken by Sir William Mac Cormac, F.R.C.S., chief surgeon of St. Thomas's Hospital, London, who was one of the Royal Commissioners under Lord Morley who inquired into the organisation of the Army Medical Service and the provisions made for the treatment of the sick and wounded during the expedition in Egypt of 1882. Sir William was accompanied on his visit by Sir Thomas Crawford, K.C.B., Director-General of the Army Medical Department; Sir Joseph Fayrer, K.C.S.I., Physician to the Council of India; Surgeon-General W. S. Murray, Principal Medical Officer at Netley; Surgeon-General W. C. Maclean, C.B.; Professors Wm. Aitken, F.R.S., F. de Chaumont, F.R.S., and D. B. Smith, F.R.C.P.; Brigade Surgeons Blatherwick and Mackinnon, Surgeon-Major Welch, and the Medical Staff of the Hospital; Mr. James Cantlie, F.R.C.S., surgeon to Charing-cross Hospital, and a goodly gathering of ladies.

Professor AITKEN said it had been usual for his colleague, Professor Longmore, to discharge the function which now, in his absence, fell to his lot, of announcing the results of the work of the past session of the school and the names of the successful competitors for the prizes, but the Queen had commanded his presence at Osborne to-day in order that she might confer upon him the honour of knighthood (loud applause). While they regretted his absence from this ceremony, at which he had always heretofore been present, he would ask them to join their congratulations with his own and unite in the wish that Sir Thomas Longmore might have health and happiness for many years to come to enjoy with Lady Longmore the well-earned honour Her Majesty had been pleased to bestow (loud applause). Professor Aitken then presented the lists of surgeons on probation who were successful at both the London and Netley examinations, with the combined number of marks gained by each, the fifty-second session of the school being marked by a large number of successes—viz., 16 for the Indian Army Medical Service and 59 for the British Army Medical Service.

Sir WILLIAM MAC CORMAC, having handed the prizes to the recipients, addressed the school, remarking upon the great pleasure it was to come in contact with a number of young men just starting as they were on a career in life, well equipped for the race, and determined, he hoped, to achieve what distinction they could in the profession of their adoption. The list which had been presented showed there were amongst them many earnest workers, and in many instances the prizes had been won in a remarkable manner, the number of marks gained being very large in proportion to the total number obtainable—viz., 7800. Whilst heartily congratulating the winners of the prizes, he reminded them it was the effort they had made—and no doubt it had been a great one—which was the real prize, for that effort would no doubt increase as years went on, and lead to still greater distinction. Every branch of the army now, he conceived, was working harder than it used to do; it was no longer entered as a mere pastime or amusement, and should it be said for a moment that the Medical Department of the army was less seriously at work than other branches? Their position in the army was, he showed, a more responsible one, and vested with greater authority, and they had to proceed in the direction of guiding others; therefore it behoved them to exercise careful judgment, as well as diligence, in their profession. They had the advantage over the civil profession of an infinite number of subjects, and an acquaintance with the life-history of their patients; therefore their opportunities for gaining knowledge with experience were exceptional. He thought he might say, in regard to the army medical officer, that he should be a good all-round man, and try to learn every branch of his profession. He believed, too, he was justified in characterising it as a mistake for a young man to devote himself at an early period of his career to some specialty, for he was apt thereby to neglect the general knowledge he would otherwise attain. Indeed, in his opinion, one could not be a specialist in the true and proper sense of the term without having a thorough good general scientific knowledge of the various branches of their profession. They were a little too much overridden by specialism just now. The human body was divided into so many square inches, and certain gentlemen thought, and tried to make others think, they knew more about certain parts than anyone else. But he advised them, valuable as it was in certain cases for a medical man to devote himself to the special study of certain diseases, not to trouble themselves at first about them exclusively, but as they went on in life they would find themselves naturally taking more interest in some special branch of medicine or surgery, for he maintained that a good all-round man was one of the best of medical men, and that was the main idea they should put before them.

The DIRECTOR-GENERAL proposed an expression of thanks to Sir William Mac Cormac, whom he characterised as a brilliant ornament to the medical profession, and also a distinguished ambulance surgeon (applause). He congratulated the surgeons on probation on having gained their commissions, and said he trusted after rising high in their profession they would be able to go out of the service with those commissions as pure and stainless as they were on the day on which they entered it (applause).

The proceedings then terminated, and a luncheon was afterwards served in the adjacent officers' quarters.

MADAME PATTI has announced her intention of giving another evening concert at the Albert Hall, Swansea, on August 19th, for the joint benefit of the Swansea General Hospital and the poor throughout the neighbourhood of Craig-y-nos Castle, her Welsh seat.

THE LANCET.

LONDON: SATURDAY, AUGUST 7, 1886.

THE year 1886 marks a new departure in regard to the Hospital Sunday Fund. The prolonged and intense depression of trade has resulted in much embarrassment to most charities, hospitals not excepted; and it does not admit of doubt that, but for special pains and efforts, the Hospital Sunday collection would have been seriously deficient. Happily, it is likely to be in the end five or six thousand pounds over the sum raised in 1885. Last year the total sum available for distribution was £33,444; this year the amount available for distribution is £38,800, and more will yet come in; the whole sum cannot well fall short of £40,000. We are not disposed to utter any undue eulogy over this achievement. Nobody is more alive than we are to its shortcomings. The sum mentioned includes £1000 from one individual. And it is inconceivable that one individual can do the fortieth part of the duty of the churches of all London on this most Christian Sunday of the whole calendar. The fact that not one other individual in five millions was induced by the proposal of Dr. WAKLEY, to give £1000 to support 154 institutions, any one of which would be worth such a subscription, is very curious. There are not a few millionaires in London, men who would not willingly let any Lazarus full of sores lie at their gate untended; but practically this is what it comes to. Sir SYDNEY WATERLOW has demonstrated it. Out of 6412 beds in London hospitals for the reception of Lazaruses, 1559 are unoccupied for want of funds. A third of all the beds in convalescent homes (758) are unoccupied for want of money. It is a proof that money is exceedingly scarce, or that it is difficult to get at, or that we have not yet succeeded in impressing the people who can give with the urgent needs and the great merits of the institutions for which a Sunday in the finest month of the year is well set apart. After making all due allowance for the hardness of the times, for the distraction of men's minds by an unprecedented political crisis, we have to say that the result is inadequate to the case. But let us not be misunderstood. We are getting on, in spite of all the above reflections, which we feel bound to make.

The money raised is thousands over the sum of last year. And the money raised is the least part of the work of the Hospital Sunday year 1886. We have had some noble exhibitions of personal service in the cause of hospitals. The Lord Mayor of the year has been most zealous in the work. His personal trouble has been immense. He has been unwearied in his attention to details, as well as eloquent in his advocacy of the great cause in public. The "Suggestions" which originated a few months ago with Dr. WAKLEY, and which in his absence from illness have been so ably carried out by Mr. BURDETT, involved a great amount of labour. Mr. BURDETT was the medium of communication of these Suggestions to the Council, of which he is a member. He with others, who will be mentioned further on, were appointed by the Council to carry out these suggestions. He assisted materially in the preparation and organisation of the six "hospitals week" meetings in the different districts, attending them all; and finally, as must be known by his name being upon the title-page of our reprints of the three Hospital Sunday Supplements, he materially aided us in their production, and, we may add, thereby largely promoted the success of this year's collection on behalf of the Fund. The series of public meetings were presided over or addressed by the busiest men in the State and in professional and commercial life. Lord SALISBURY and the Duke of CAMBRIDGE found time in the very thick of an election contest to attend one of the best hospital meetings on a Saturday night at the Stratford Town Hall. The ministers of every church and creed in London have exerted themselves to increase their individual collections. The services, too, of the energetic Secretary of the Fund, Mr. CUSTANCE, must not pass unmentioned, nor those of the Special Committee appointed to carry out the arrangements of the "Hospitals Week," which consisted of the following gentlemen:—The Right Hon. JOHN STAPLES, F.S.A., Lord Mayor, President; Sir SYDNEY WATERLOW, Bart.; Sir J. RISDON BENNETT, M.D., F.R.S.; Sir EDMUND HAY CURRIE; HENRY C. BURDETT, Esq.; THOMAS CHRISTIE, Esq., F.L.S.; J. G. GLOVER, Esq., M.D.; J. LAWRENCE HAMILTON, Esq.; the Right Rev. the Bishop of BEDFORD and EAST LONDON; the Rev. Canon FLEMING, B.D.; the Hon. REGINALD CAPEL; the Rev. HENRY ALLON, D.D.; the Rev. JOHN KENNEDY, D.D.; the Rev. WALTER MORISON, D.D.; the Rev. J. H. RIGG, D.D.; the Rev. ANDREW CROMBIE; the Rev. R. J. SIMPSON, M.A.; the Rev. Professor MARKS; and RICHARD. B. MARTIN, Esq. The general result is an increase of thousands in the collection. This is something, but it is far less in value than the information which has been spread and the interest which has been excited in the cause of hospitals. When the public know, as they now do, the want of money and the empty beds, good must inevitably result. When they know that the Council of the Hospital Sunday Fund goes minutely and even critically into the merits and the needs of each hospital and dispensary, and that the result is that only in the case of one institution was an award withheld for mismanagement, and that a dispensary, they will decide, we feel sure, to give more and to leave more to hospitals. One other consideration will confirm this determination—the enormous amount of unpaid and voluntary labour given by busy men to the administration of hospitals. So we leave the best Hospital Sunday year yet realised. All who have laboured in connexion with it will reflect with satisfaction on the money or the time they have given to it. We feel sure they have raised the whole argument for hospital support to a much higher level than before, and that the year 1886 will be remembered in the annals of hospitals.

INTERESTING as is the study of the lesions of the valves of the heart, their importance is as nothing compared with the muscular wall of that organ. Pathological anatomy and clinical medicine present great contrasts in this respect. In the post-mortem room a minute description of the state of the valves is generally forthcoming, whilst the state of the myocardium is usually dismissed in a few words. But

the matter is altogether different at the bedside. The condition of the heart muscle represents in many respects the state of the patient himself. Hence the extreme importance of the cardiac tonics. The class of cardiac tonics is a very large and heterogeneous one. It includes all the varieties of alcohol, ammonia, and ether. But the chief therapeutical interest centres around digitalis and its congeners. The literature of the specific cardiac tonics alone would fill a small library, and yet there is by no means a general consensus of opinion as to the relative values of the different drugs in the treatment of the various valvular lesions.

Dr. JAMES BARR is performing a great service to the readers of the *Liverpool Medico-Chirurgical Journal* by drawing up a report on the cardiac tonics. Failure of compensation manifests itself in a great variety of ways, but the general meaning of this failure is the same in all cases, and therapeutically calls for certain remedies. There can be no question that the remedy of greatest value is rest in the recumbent posture, and this alone is sufficient to restore, at least for a time, the compensation. It should be tried alone in all cases, if we are to judge accurately of the value of the different cardiac tonics. If it do not succeed alone or in combination with supporting diet and stimulants properly regulated, resort must be had to specific medicines, and the one chosen will vary with the nature of the valvular lesion and with the kind of complication which the failure of compensation has brought about. Take the case of mitral regurgitation. In such a lesion, with failing power of the heart muscle, digitalis will answer best in the vast majority of cases, but not in all. Caffeine, on the other hand, often seems to act with more efficiency when dropsy is the chief sign of failure. And we are of opinion that in dropsical effusions the active principle of coffee would prove the better agent when these are the result of heart debility. Some individuals cannot imbibe digitalis without being injuriously affected, irrespective of its action on the myocardium. Many nervous symptoms appear which were not present before, and which almost certainly are to be ascribed to the deleterious effect of the drug. Further, the drug may depress the activity of the myocardium, or even render the irregularity of its action still more manifest, increasing rather than removing the serious symptoms. It is impossible to predict in which cases these untoward results will occur, and the commencement of the administration of the agent therefore calls for considerable attention on the part of the prescriber. The cases in which convallaria will prove useful when digitalis and caffeine have failed we have found to be few in number. Mitral stenosis pure and simple is a lesion which is peculiarly difficult to be relieved by any of the drugs in present use. Most frequently, in our experience (in uncomplicated cases), the dyspnœa is the severest symptom, and certainly due to the enormous engorgement of the pulmonary vessels. Nature is generally, however, equal to the occasion, and the free hæmoptysis should rather be encouraged, whilst the bed is strictly kept and copious catharsis induced.

Dr. BARR extols the use of nitro-glycerine in mitral stenosis on grounds the strict logic of which we do not perceive. He correctly points to the over-distended pulmonary circulation, and then to the tension of the not very full systemic arteries. Nitro-glycerine, which is to be preferred to the sodium nitrite and indefinite sweet spirits of nitre, is to be given because it dilates the arterioles, and thus tends to draw more blood to the arterial system; we are disposed to allow all this, but does the dilatation of the arteries diminish the tension in the pulmonary system of vessels? That nitro-glycerine is of value in mitral stenosis we know from experience.

Although we do not think that digitalis is contra-indicated in aortic regurgitation, there can be no doubt that it is a far less valuable agent in that condition than in mitral affections. A great deal of the uncertainty of the action of digitalis may be explained by reference to the state of the myocardium; when this structure is embarrassed in its functions by fatty degeneration of many of its fibres, or when fibroid degeneration, often spreading in from an adherent pericardium, hinders its action and nutrition, cardiac tonics act at a disadvantage, the real nature of which is only discovered at the necropsy, though during life it was supposed that the case was an illustration of idiosyncrasy. Irregularity of cardiac action, not being always a sign of cardiac failure, is apt to be met with under conditions which, not calling for the tonic effects of digitalis, give the case the aspect of a pure neurosis, and yet the same drug will often regulate the rhythm, or even remove positive intermittency.

THE mountain cure of phthisis has established itself as a genuine therapeutic advance. We are still without definite data regarding the classes of cases to which it is applicable, although a notable advance is being made in th s direction, and we have not yet fully determined the precise measure of its efficacy; but it is no longer doubtful that in a certain number of cases, be they large or small, its value is indisputable. Let us consider for a little on what its efficacy rests, and whether theoretical considerations are in harmony with practical experience.

Phthisis being the respiratory disease *par excellence*, the most fundamental condition of cure is a favourable state of the air which the patient breathes. Good air is not the sum and total of the therapy of phthisis, but without it all other measures are likely to prove ineffectual. The atmosphere at high altitudes possesses three marked characteristics—viz., purity, rarefaction, and cold. All modern observers are agreed that pure air is the most essential requisite in the treatment of the national scourge, and this belief does not depend on, although it is strengthened by, an acceptance of the views of KOCH regarding the important part played by the tubercle bacillus. Whether foul air acts as a nidus for the peculiar virus of the disease, or operates injuriously by promoting the putrefaction of discharges and intensifying the activity of ulcerative processes in the lung, or lastly by merely impairing appetite and hindering nutrition,—in view of any or all of these theories, its unquestionably pernicious influence is readily explicable. Pure air is not to be found near the great centres of human population, nor even in ordinary lowland country. To obtain it in perfection we must look to the ocean, the desert, or to high altitudes. In these three localities we are far removed from the ordinary sources of atmospheric contamination, and it is hardly

necessary to seek to assign any precedence among them, as in each case the atmospheric purity is practically absolute.

The next and most essential characteristic of the air at high altitudes is its rarefaction, which is of course proportionate to the elevation. Speaking broadly, rarefaction is but slightly appreciable at any elevation under 2000 ft., but becomes marked at every rise of 1000 ft. above this level. The favourite Swiss sanatoria for phthisis, such as Davos, St. Moritz, Samaden, Pontresina, &c., are at elevations of 5000 ft. and upwards. In the Andes the sanatoria are at much higher altitudes, Bogota, Areguipa, &c., being from 9000 ft. to 10,000 ft. above sea-level. The first effect of rarefied air upon the lungs is to provoke deep and full respirations, thus promoting pulmonary expansion and affording a favourable condition for the absorption of morbid deposits. It is evident that such conditions might be expected to exercise a favourable influence upon phthisis. The fact that tubercle has by preference its seat in the apices, the least functionally active part of the lungs, is a hint to us that in the treatment of the disease we should seek to promote activity, and not quiescence, of the pulmonary organs. The great difficulty is, no doubt, with the hæmorrhagic cases. Rest is wisely enjoined where hæmorrhage exists or is threatened, but it seems no less certain that the deposit of tubercle is favoured by an invalid life of sedentary inactivity.

At Davos, phthisical patients who have suffered from hæmoptysis are, after a time, encouraged to engage in skating, tobogganing, and other active out-door amusements, and statistics show that mischief rarely results from so doing. The free circulation of blood throughout the entire system no doubt involves a vigorous flow through the vessels of the lung, but it should not be forgotten that it has the important advantage of preventing pulmonary stasis and congestion. It was long believed that rarefied air tended to promote hæmorrhage, and in confirmation of this view well-authenticated stories were related of the sufferings of mountaineers from epistaxis and melæna. It is not necessary to dispute the accuracy of such facts, but when they are brought forward in support of the view that hæmorrhagic phthisis is likely to be unfavourably influenced by resort to high altitudes, it is forgotten that the conditions of blood-pressure at the various orifices are different from those which prevail in the internal organs. The congestion at the surface of the body must be accompanied by a proportionate anæmia of the deep-seated parts, and among them of the lungs. Hence rarefaction of the air, so far from being injurious in cases of pulmonary hæmorrhage, affords a means for its arrest and relief.

Cold is the third important characteristic of the air at high altitudes. It was long believed that warmth *per se* had a favourable influence upon phthisis, but this theory is now quite abandoned. Tuberculosis is common in tropical regions, whereas it is extremely rare in polar latitudes. Warmth no doubt favourably influences the bronchial catarrh which is so general an accompaniment of phthisis, but it has no beneficial effect upon the tubercular deposit. Fortunately the air at high altitudes is not only very cold but very dry, and this combination of conditions tends to check unhealthy secretions, while at the same time it is promotive of appetite and physical activity. This last point is one of great magnitude. No climate can permanently benefit phthisis unless it tends to improve nutrition, and it is one of the chief claims of the high altitude resorts that most patients, with the exception of those who do not possess sufficient vital energy to react to the stimulus of the cold, acquire during their residence among the mountains a great augmentation of appetite and digestive power.

We content ourselves for the present with merely explaining the *rationale* of the high altitude treatment in favourable cases. That it often fails, and that many cases are unlikely to benefit by it, is undoubted. Further experience is necessary before we can take the full measure of its usefulness, or assign definite limits to its applicability.

THE subject of Public and International Hygiene is likely to occupy an important place in the discussions of the ninth International Medical Congress, or rather of its fourteenth section. We are glad to see that Mr. SIMON is anxious to attend the Congress and take Vice-Presidentship of the Section. Mr. SIMON, indeed, speaks in his letter responding to the invitation with some doubt as to his power to attend, but with a clear intimation of his desire to do so. Dr. B. W. RICHARDSON and Dr. THUDICHUM both reply in most cordial terms to similar invitations, and accept a similar office. To those who know the imperfect health which Mr. SIMON has lately enjoyed, the significance of his conditional acceptance is very great. The promoters of the Congress will take this as a sign of British goodwill towards their great and responsible undertaking. The important subject of International Quarantine is to be raised by the president of the section, JOSEPH JONES, M.D., of New Orleans. We could send to the discussion of such a subject no greater authority than Mr. JOHN SIMON. We are glad to be able to report a very general desire among leaders in London to be present at Washington in 1887. Whatever hesitation they felt some time ago in view of the divided state of feeling in America is now steadily giving place to a desire for the success of the Congress, and a wish to do anything they can to further it. We feel quite justified in saying that our best men in England and Scotland are preparing to go if they get any indication that their presence will be acceptable. Sir JAMES PAGET, Sir ANDREW CLARK, Sir SPENCER WELLS, Professor JOHN CHIENE, Professor FRASER, and we believe Sir WILLIAM TURNER, are all, according to our information likely to go.

It is not America alone that is interested in the success of the meeting at Washington, but the profession throughout the whole world, and we might add the world itself. When our profession meets internationally it is of good omen. We not only stimulate fraternity and scientific rivalry amongst ourselves, but every thought in advance and every medical discovery is a great boon for the human race and for all nations. We urge on members of our profession in the empire to strain a point to be at Washington on or before September, 1887, where, if report is to be trusted, a very hospitable reception awaits them.

Annotations.

"Ne quid nimis."

CHOLERA IN SOUTHERN EUROPE.

AUTHENTIC news as to cholera from the south of Italy has almost come to an end during the past week, Manduria being the only place from which any definite returns have been received, and even these have been irregular, and they came to a sudden stop on July 31st. Between the 28th and the 31st there had, however, been 83 fresh attacks and 19 deaths there. In Brindisi we also learn that the disease is not yet entirely subjugated, but that the decrease in the epidemic there is so marked that bulletins as to it have been discontinued. Whilst, however, this decrease has been in progress in the south, there has been a further extension of cholera in the north-east of Italy. In the province of Treviso, the capital of the same name and the towns of Castelfranco and Montebelluna have become infected since the beginning of August, and up to the 3rd of the month there had been 4 deaths in Treviso, 7 in Castelfranco, and 13 in Montebelluna. In the adjoining province of Vicenza there have been 8 deaths at Citadella, and there was also a report of 48 cases at Arzignano. In Verona, the city of that name has, during the three days ending August 3rd, had 9 attacks and 1 death; and in Padua 17 cases are stated to have occurred. Immediately to the south in the province of Rovigo, Chioggo, situated on the southern shore of the lagoon of Venice, is reported to have had 22 attacks and 7 deaths, and at Cavazere, to the south of the lagoon, but in the marshy ground which characterises the mouths of the Po, 23 cases and 1 death occurred during the two days August 2nd and 3rd. Coming somewhat further south into the province of Ferrara, cholera still hangs about the southern mouths of the Po, 27 fresh cases and 8 deaths having occurred at Codigoro, and 9 cases and 4 deaths being reported from Lago Santo; whilst in Ferrara itself 4 cases and 3 deaths are stated to have taken place. In Ravenna, 79 cases and 36 deaths have occurred between July 29th and August 3rd, and during the same six days 75 cases and 38 deaths have taken place in Bologna. There are also reported 22 cases and 3 deaths respectively from Cucca and Pescantina. During the last two days of the week under consideration there has also been a resumption of the cholera bulletin from Venice itself, 4 more cases and 1 death having been reported from there. In all, news has been received during the week ending August 3rd of 535 fresh attacks and of 152 deaths from cholera in Italy; and this is admittedly not a complete record of the effects produced by the epidemic. The most striking events of the week are the still further diffusion of the disease in the north-east, where it is most severely felt at Ravenna, Bologna, and Castelfranco, and the sustained severity in Manduria to the extreme south. So far as the Austrian Empire is concerned, the only additional locality where cholera is specifically stated to have occurred is Socesga, in the district of Capo d'Istria, immediately to the south of Trieste; but at the same time the disease is maintained at Trieste, 38 fresh cases and 7 deaths having occurred during the week under consideration. As regards Fiume, where 17 and 6 fresh cases and deaths respectively have taken place, it is said that it has formed a centre whence the disease has spread to several of the neighbouring villages. A sanitary inspection is now required at the Hungarian frontier as regards all goods travelling from Trieste and Istria. Summarising the total effects of cholera in Trieste up to July 28th, a correspondent states that there had been 89 cases and 53 deaths in that city.

DR. GLOVER AND THE MEDICAL COUNCIL.

WE report in another column the proceedings of a meeting of north London practitioners and a few others, which was called to consider the propriety of laying before the profession the claims to a seat on the Medical Council of Dr. J. Grey Glover, of Highbury. It was unanimously decided to ask that gentleman to allow himself to be nominated at the forthcoming election of Direct Representatives, and the meeting of his neighbours and friends pledged themselves to do their utmost in his behalf. Elsewhere will be found Dr. Glover's address, and a preliminary list of his committee of supporters. We are very glad that Sir Andrew Clark, who spoke at this meeting, gave advice which, in our opinion, is most sound. He stated that the great aim of enacting direct representation of the body of the profession on the Medical Council is to enable the general practitioners to express their views and exert their just influence upon medical education and legislation. Already the various teaching and examining bodies, and the consultants, are fully if not over-represented, and the aim of the great mass of electors should be to send men of their own body who by their character, experience, and ability are able really to represent them. We need not conceal the fact that the gift of direct representation has enemies in some influential quarters who will closely watch its earliest results; and for this, among many other reasons, it is all-important that the outcome of the first election should be the return of members to the Council who are able to speak for the great body they will represent with undoubted authority. The election of general practitioners is, however, attended with one great difficulty in that the members of this branch of the profession—the largest and in many respects the most important—have but little opportunity of making themselves known far beyond the district in which they live. This being so, the opinion of a candidate's neighbours must have very great weight. It is eminently satisfactory, therefore to find that the invitation to Dr. Glover emanated from those who are most closely associated with him in the profession, and who have the best opportunities of judging of his ability to serve them on the Council. His neighbours are unanimous in his support; and this fact is one of the strongest possible arguments in his favour. But Dr. Glover has other strong claims upon the suffrages of the profession. He has for years interested himself in a very practical way in the work of the Medical Council; he has been a very frequent visitor at its meetings, and is familiar with its procedure and the duties imposed upon it as defined by Act of Parliament. He would therefore be able to take his seat at the Council fully equipped to enter upon its business, and would not have to undergo any preliminary training. Dr. Glover showed his thorough acquaintance with medical politics in the evidence he gave before the Select Committee and the Royal Commission on Medical Education, and it is clear that his evidence had great weight on both occasions, and its influence was apparent in the reports presented to Parliament. Further than that, Dr. Glover is a man of unimpeachable personal and professional character, who will in himself represent what is truly best in the great body of general practitioners. He is a graduate of the University of Edinburgh, but has been in general practice at Highbury for many years, where he has won the respect of all his neighbours and has attached to himself many friends in all ranks of the profession. In sending Dr. Glover to the Medical Council, the profession will carry out the true intention of the framers of the Act in the best possible way; it will strengthen that body just where it needs strength most, and it will put a high honour upon one worthy to bear it, who has not sought it, who will use it independently, and for no merely personal or sectional ends, but will ever try to advance the wellbeing of the entire profession.

SIR JOHN LUBBOCK ON THE STUDY OF SCIENCE.

THE address delivered by Sir John Lubbock on the occasion of unveiling the statue of Sir Josiah Mason at Birmingham is reproduced in the current number of the *Contemporary Review*, and will be read with interest by all who are concerned in the promotion of the study of science. It is needless to say that the eloquent address of the member for the University of London was a masterly plea for the pre-eminence of science in the curriculum of a liberal education; and it is equally unnecessary to add that, while bestowing well-deserved praise on the labours and success of his own university, Sir John Lubbock did not allow the opportunity to pass without girding at the universities of Oxford and Cambridge for their alleged neglect of science. Pointing to the facts recently embodied in a return to a motion he made in the House, Sir John stated that, of 240 schools, in 54, or over 20 per cent., no science whatever was taught; in 50 only one hour a week was devoted to science; in 76 two hours, or less than three; while out of the whole 240 schools only 6 devoted to the study of science as much as six hours a week. "In short, it is clear, therefore," contends Sir John Lubbock, "that, in spite of all which has been said, very little progress has been made in this respect. Our schools are generally more industrious; but, remarkable as it may appear, Latin and Greek absorb more time than ever." This is a state of matters which the leading "champion" of science in education, of course, very greatly deplores. There may be differences of opinion on the comparative merits of the study of languages with all this contingently implies, and of the study of science, as agents in mind-culture; but as regards the main issue, there cannot, we venture to think, be any difference. All must feel the need of a better knowledge of scientific subjects, and desire to see the study of science extended. We do not, however, entertain the optimist views of Sir John Lubbock on the subject of science as a regenerator; nor do we share his opinion that "the study of natural history seems destined to replace the loss of what is *par excellence* termed 'sport,' engrained in us, as it is, by the operation of thousands of years during which man lived greatly on the produce of the chase." This is not a disposition of Destiny towards which we can look with yearning or even complacency. The race will never be ennobled, or the glory and independence of the nation increased and consolidated, by the development of a sentimental love of nature or of science. Englishmen must still love the gun and the chase, if they are to be robust as well as "learned." It would be a dark day for the land if the majority of the population should betake itself for pastime to the study of science. It is well that there should be hobbies and hobby-riders, or there would be no struggle for the pre-eminence of the several branches of enterprise, but, in all seriousness, the gentler arts must not be pushed to the neglect of the more *manly*.

PERIPHERAL NEURITIS AND TABES.

THE interesting fact that tabes dorsalis is often associated with, and even preceded by, lesions of a peripheral rather than a central kind has attracted much attention of late. We have before mentioned the contribution made by M. Pierret to the Academy of Medicine, and we may now add the conclusions arrived at by MM. Pitres and Vaillard from a study of many cases (*Rev. de Méd.*, July, 1886). These statements are to the effect that the peripheral nerves of tabetic subjects are often the seat of indubitable inflammatory changes in no way differing from other forms known as non-traumatic neuritis. The changes are very variable in their situation; the sensory, mixed, and visceral nerves may be attacked. In the majority of cases, but not in all, the neuritis begins at the terminal extremities of the nerves. The extent and gravity of the changes bear no constant relation to the age, extent, or depth of the spinal lesions of locomotor ataxy; nor do they apparently take any share in the special symptomatology of tabes, as the lightning pains, motor incoördination, abolition of knee-jerk, and disorder of muscular sense—symptoms which seem to be due to the sclerosis of the posterior columns and the posterior nerve roots. On the other hand, there are certain rarer symptoms which seem to be directly related to peripheral neuritis; such are (*a*) areas of cutaneous anæsthesia or analgesia; (*b*) trophic skin lesions, as perforating ulcer, œdema, eruptions, dystrophy of the nails; (*c*) certain motor paralyses, accompanied or not by muscular atrophy; (*d*) arthropathies and spontaneous fractures; and in some cases the visceral neuralgiæ may be attributed to neuritis of the corresponding nerves.

REPORT OF THE SCOTTISH COMMISSIONERS IN LUNACY.

THE General Board of Lunacy in Scotland has the merit of recognising that there are such persons as "unreported lunatics maintained in private dwellings from private sources," and therefore forbears to claim a thorough knowledge of the whole field of lunacy in Scotland. This recognition is the key to what we conceive to be the better method of statistical work and inference adopted by the Scottish Commissioners when their work is compared with that of the English. Speaking of the alleged "increase of lunacy" so-called, the General Board says, "We have frequently pointed out that the difference in rates of increase does not necessarily indicate an increasing amount of mental disease, and that it is probably due in large measure to what is only an increasing readiness to place persons more or less disordered in mind as lunatics in establishments." On the 1st of January in this year, 1886, the total number of lunatics under official cognizance in Scotland was 11,187, showing an increase of registered lunatics during 1885 of 268. The total increase of pauper patients rose 271, while that of the private patients fell 3. There is nothing specially worthy of notice in the twenty-eighth report of the Scottish Commission, unless it be its very late appearance, the date on the title page being "February 24th."

THE PROPOSED HOSPITAL AT DARENTH.

THE Metropolitan Asylums Board have again had under consideration the desirability of erecting a permanent hospital for small-pox on their land at Gore Farm. The plans for this hospital were prepared a long time since, and these plans were approved by the Local Government Board, but after additional evidence had been placed before the Board of the injury inflicted by small-pox hospitals to their surrounding neighbourhoods, the Local Government Board recommended that only a temporary hospital should be erected, and based this recommendation on the uncertain state of medical knowledge. The Metropolitan Asylums Board, however, at their last meeting, expressed dissatisfaction with this opinion, and determined to request the Local Government Board to at once issue the order promised in their letter of July 12th, 1884, authorising the Managers to expend and raise on loan the sum of £116,000, being the amount which it is estimated will be required for the erection of the proposed hospital for convalescent small-pox patients on the Managers' estate at Darenth. It was urged at the meeting that the difference in cost of the erection of permanent and temporary structures was so slight that the saving was of no practical value compared with the great disadvantage resulting from a temporary building. These proceedings

are somewhat perplexing. The Local Government Board have in their possession ample evidence that the aggregation of cases of small-pox in the acute stage of the disease gives rise to small-pox in the surrounding neighbourhood. The fact as to the aggregation of convalescents is less obvious, but it may, we imagine, be assumed that some number of persons who cannot be accurately described as convalescents will, as in past times, be received into the hospital. The real question at issue is, therefore, whether hospitals can be so constructed and administered that they shall not be a source of danger to residents in their vicinity; whether they be temporary or permanent does not affect this question. If the Local Government Board are not satisfied with the position of medical knowledge on this subject, they have it within their power to make further investigation; but by the adoption of a policy of procrastination the money of the ratepayers will undoubtedly be sacrificed, and their lives may be imperilled.

LIGATURE OF THE EXTERNAL ILIAC ARTERY.

THE "Observations on Aneurysm and some Diseases of the Arterial System," by Mr. George Freer (Birmingham, 1807), is one of the classical surgical monographs well deserving study. It embodies the results of experimental research, a digest of Guattani's treatment of aneurysm by compression, and a record of the first case in which the external iliac artery was tied successfully. Freer's assistant was no other than Joseph Hodgson, who beautifully illustrated the memoir, and was soon to become famous as the author of the "Treatise on the Diseases of Arteries and Veins" (1815), which was for many years the standard work on the subject. The external iliac was first tied by Abernethy, and he performed the operation four times, but only his last two patients lived; the first of these was rare, as one of the very few cases in which the procedure has been practised on a woman. Astley Cooper had four successes in six, but Mr. Bryant of Guy's has done the operation six times without a death, and, Mr. T. H. Bartleet has successfully tied the external iliac artery three times at the General Hospital, Birmingham. His patients were males, of the respective ages of thirty-one, thirty-three, and thirty-eight years. In his second case Mr. Bartleet tied the iliac for secondary hæmorrhage after ligature of the common femoral. His third case was operated on with stout catgut, cut short, on June 29th ult. The wound healed almost completely by the first intention, and convalescence has been rapid and uneventful.

INSANITARY BURIALS IN ST. MARY WOOLNOTH.

NOTWITHSTANDING that our sanitary arrangements in the present day are sometimes far from perfect, we are fortunately exempt from some of the excesses of mismanagement which prevailed in a former generation. We still bury our illustrious dead in our great churches, but such an occurrence is necessarily rare, and injurious rather as an example than in itself. Vaults and perennial coffins remain among our cherished abuses, but science is dealing heavy blows against their stability. We are learning the laws of funeral hygiene, and are at least endeavouring to apply them. Nor has the change to a rational procedure come a day too soon. We may illustrate these remarks by a reference to the state of the church of St. Mary Woolnoth, now undergoing repairs. Complaints have been made for some time past of the bad smells which prevailed in that building, and were supposed to come from the church vaults. On examination hundreds of bodies undergoing decomposition were found beneath the floor. The last of these was buried, or rather entombed, many years ago; but from the conditions of interment, they with their massive coffins are still decaying, and are thus late yielding to worshipping congregations the gases of putrefaction. No stronger argument could be brought against the still existing custom of burial in churches or vault burial in general—no clearer proof that earth alone must receive our bodies after death. The local vestry will not, we hope, forget the teaching of experience, that thorough disinfection must accompany all the work of repair at St. Mary's if disease is to be surely prevented. The plan of hermetically sealing the whole burial area with concrete, as has been suggested, is an excellent one, which has already stood the test of practice and of time.

LEAD IN TINNED PROVISIONS.

DR. RABCHEVSKI of St. Petersburg has published the results of a series of investigations made on various kinds of tinned provisions, with the view of determining the suitability of food preserved in this way for the purposes of the army commissariat, especially when on active service. He first examined the tinned plates in the preserved provision manufactories, and found them in all cases quite free from lead. The case of the solder was of course different, the amount of lead contained in it varying from 60 to 70 per cent. The chemical examination of the contents of the tins was conducted by Pouchet's method, and showed that while some classes of food, such as roast meat, were quite free from lead, others, such as sour cabbage, which to a Russian is a very important article of diet, contained very appreciable quantities of lead, in one case as much as 0·327 per cent.; so that a man taking 200 grammes, or about a quarter of a pound, of this for his dinner would introduce into his system 0·654 grammes, or about eight grains, of lead—a quantity which, especially if taken frequently, can by no means be considered as harmless. The conclusion arrived at by the author is that these tinned provisions should only be used in the army in case of urgent need, and for a very short time. It would appear, too, that a choice might be made, only such classes of preserved food being accepted by the authorities as were shown to be least likely to become contaminated by the injurious substances contained in the solder.

PHYSICAL TRAINING OF CHILDREN.

LORD BRABAZON, the Chairman of the Metropolitan Public Gardens Association, has, on behalf of this Association, addressed memorials to the Royal Commission on Education and to the London School Board, urging that the code of education should be so altered that physical training shall be included among the obligatory subjects, and in this way necessarily introduced into each department of every elementary school. The proposal has our sincere sympathy. Mental training is now being pushed to an extent that renders it the more necessary that every effort should be made to improve the physical condition of children, who are having a strain put upon their nervous system which is greater than can be easily borne by the ill-developed inhabitants of large towns. The necessity that the English people should not be behind those of other countries in education makes it very desirable that their health should be improved, to fit them to pass through the process without injury, rather than that their teaching should be less thorough; and Lord Brabazon has, we believe, suggested an excellent method by which this can be effectually done. The memorials point out that playgrounds in connexion with the schools under the Board should be kept open for the use of the children and young people of the neighbourhood, under proper supervision, between and after school hours; and that covered gymnasia and an increased supply of gymnastic apparatus in the playgrounds should be provided, with proper instruction in the use of such apparatus. The memorials refer

to the need of some fund for the maintenance of existing playgrounds and the great difficulty which exists in obtaining in densely populated districts adequate open spaces for public recreation. The ratepayers feel acutely the heavy tax which is put upon them for the education of the poor, and there is probably no way in which the burden of the necessary outlay can be rendered more acceptable than by enabling Board schools to be made more generally useful to a larger number of those who contribute towards their maintenance.

SOFT CHANCRE OF THE MIDDLE EAR.

THE *Gaseta Lekarska*, a Polish medical journal, contains a report by Dr. Guranowski of a case of soft chancre of the middle ear. The patient was a woman with a phagedænic chancre of the genitals, who from snuffing tobacco managed to introduce the virus into the nose, where the septum had become ulcerated, with copious discharge of foul pus. From this the infective material must have passed through the Eustachian tube into the middle ear. Deafness and pain were complained of, and subsequently perforation of the tympanic membrane occurred, a large quantity of purulent matter being discharged through the opening and infecting in its turn the external meatus. The case was treated by the introduction of iodoform into the ear and nose, and by injecting warm water through the ear by means of the Eustachian catheter. In a month's time the patient regained her power of hearing and completely recovered. Dr. Guranowski has a great belief in the efficacy of washing the middle ear with warm water, having seen cases of severe inflammation recover under this treatment where it was feared that the only hope of saving the patient's life lay in trephining the mastoid process.

SUICIDE FROM DYSPEPSIA.

WHY a woman suffering from dyspepsia should elect to drown herself in a water-butt is one of those inscrutable mysteries which it would tax the ingenuity of an astrologer to explain. The intercommunication of mind and body is, however, so close that nothing is really strange in the phenomena of mental symptoms dependent upon visceral irritation. Carlyle's "foul fiend-hag," dyspepsia, is capable of any vicious prank, and the vagaries of the enemy are in no way to be measured by the conventional symptoms of any disease. Hypochondriasis is a good word for popular use in such cases. It means nothing, and yet implies a great deal. But was the woman Elizabeth Rouse, who committed suicide at Paddington last week, under treatment of any kind? A tendency to suicide in cases of this class is not generally of rapid, or at least sudden, growth.

PHOTOGRAPHY IN MEDICINE.

WE are indebted to Dr. J. Ashburton Thompson of Sydney for a copy of a report which, as medical inspector, he made to the Board of Health last year, upon five cases of variola which arose in the Orient Hotel of that city in August, 1884, and were treated in the quarantine hospital ship. At the suggestion of the president of the department, Dr. Thompson took photographs of the cases, in order to convince members of the profession who were sceptical as to the diagnosis. The report is accompanied by a series of eleven photographs of the face and leg of another patient attacked later in the year, taken at various stages of the disease—viz., from the third to the twenty-fifth day. The photographs are excellent specimens of their kind, and convey in a striking manner the changes undergone by the exanthem. The case was one of "variola discreta," so that the eruption became very profuse during its progress. It may be added that the patient, a girl aged eleven years, had been unvaccinated when her mother fell ill of the disease and died. The child was vaccinated, but was attacked with small-pox a week afterwards. We are not aware that photography has ever been employed with such an object before, and Dr. Thompson must be congratulated on the success of his efforts.

ACTION OF VASO-MOTOR NERVES ON LYMPHATICS.

THE circulation of the lymph is usually regarded as dependent on more or less indefinite causes, and probably few have asked themselves the question whether the nerves have any direct influence in the process. M. Lewaschew, whose name will be remembered in connexion with the experiments of chronic nerve-irritation on vessels, has attempted to discover the influence of the vaso-dilator and vaso-constrictor nerves on the circulation of the lymph. He has studied the production of lymph in the posterior limbs of the dog under the action of the different kinds of vaso-motor nerves, and finds generally that it varies directly with the flow of blood through the limbs; so that the greater the rate of the sanguiferous circulation the greater is the production. The method of the experiments is given in the *Union Médicale*, No. 96, in a note communicated to the Académie des Sciences by M. Vulpian. It is not argued that the nerves exercise any direct effect on the lymphatics; but that is a question of hydro-dynamics. Purely physical conditions explain sufficiently accurately the observed facts. The dilation of vessels, with increased contents, is attended with an augmentation of the normal amount of exuded fluid which escapes from the limb through the intermediation of the lymphatics, in which of necessity the stream becomes more rapid, and from which in consequence the quantity of fluid flowing away in a given time is considerably increased.

OPERATION FOR RECTAL CANCER.

DR. ARTURO GUARNERI relates, in the *Gazzetta degli Ospitali* of July 14th, a case from Volkmann's clinique, illustrating very forcibly the modern practice of attacking cancer of the rectum with the knife. The patient, a single woman, aged twenty, had undergone extirpation of the rectum for epithelioma. The disease having returned, some more of the intestine was removed with a large portion of skin, part of the vaginal wall, and a piece of the ischiatic tuberosity. The peritoneum was opened; nevertheless the patient recovered almost perfectly, and a plastic operation was subsequently performed to shut off the vagina and reconstruct the perineum. A detailed history of the procedure and of the final issue could not fail to be instructive.

FREE TRADE IN ADULTERATION.

IF any fresh evidence of the absurd state of the law in regard to adulteration were required, it would be furnished in abundance by the recent Stratford cases reported in, and most fairly denounced by *The Times*. Three tradesmen were proved to have sold adulterated coffee, without notice to the purchaser, at prices which yielded an unreasonable and exorbitant profit. The magistrates, it seems, dismissed the summonses with the pithy remark of the chairman, that "the Court won't give no reasons." These things happen incessantly. Some magistrates strain all points in favour of the dishonest dealer. If they can let him off, legally or illegally, they do so; and if they are forced into a conviction, they impose fines that are purely nominal. Why magistrates should sympathise with traders who prey on the poorer classes, we cannot tell, but it is evident that some of them do. The Food and Drugs Acts have not been dead letters, for things are better now than when we first attacked the evil. Adulterations with poisonous materials have

become comparatively rare, and even fraudulent adulterations are under some control in a great number of places. But no certain check is imposed. The law is defective, and the administration is equally defective. The definition of adulteration is read very differently by different magistrates, notably in the article of milk, and the penalties attached to the offence differ as much. In some districts the local authorities are active, and having chosen efficient analysts, do their best to support them; but in others nothing whatever is done. Sometimes no analyst is appointed, sometimes he is not efficient, and sometimes he remains for months or years without work. When a prosecution is undertaken every possible difficulty must be surmounted, every legal quibble met, and the result is that even in the clearest cases success is so doubtful that men naturally shrink from the trial. We have no wish to subject honest traders to inconvenience, and we freely admit that it was right in the earlier days of legislation to be careful lest honest trade should be harassed. But much experience has been gained in the last few years, and the time is now ripe for the passing of an Act which, without pressing unfairly upon manufacturers, producers, or dealers, shall afford the public a much greater protection against fraud than they now possess.

PROGRESSIVE FACIAL HEMIATROPHY.

A GIRL of nineteen is mentioned in the reports of the Swedish Medical Society as having suffered from the above-mentioned disease for four years. The first symptom was continuous but not severe headache situated in the right temple, cheek-bone, and crown of the head. After three years she noticed a contortion in her face, with depression of the right temple and cheek-bone. On close examination, Dr. Würfvinge discovered that the right half of the face from the temporal region to the lower jaw was extremely atrophied, the atrophy affecting the skin, mucous membrane, muscles, fat, and bone. The muscles, however, were not completely atrophied, since they contracted at will or by faradisation. The skin of the atrophied parts could be lifted up in thin folds. The sensibility on the right side of the face was normal, and there was never any sensation of creeping or cold. There was no disturbance in the circulation of the blood; no abnormal dryness or humidity; no spots on the affected side. The colour was the same on both sides; the hair on the right temple a little thinner than on the left. The tongue was found to be thinner on one side than the other, but the taste on both sides was the same. The organs of sight, hearing, and smell presented nothing remarkable.

POISONING BY SAUSAGES.

FAMILIAR as is poisoning by sausages, there yet remains much to be learnt of the manner in which the poison or poisons act. Sometimes an inorganic poison has been suspected, but generally it is supposed that the deleterious agents are in some way related to the occurrence of decomposition in the organic contents of sausages. Nauwerck of Tübingen has investigated a series of cases of poisoning by sausages, and has come to the conclusion that the symptoms were to be largely attributed to the agency of certain complex bodies that are known to be derived from the decomposition of albumen. Some of the symptoms of sausage-poisoning are of considerable interest; such as the paralysis of accommodation for near objects of vision, also the dilatation of the pupil and drooping of the upper eyelid. It does not follow that sausages are harmless because a chemical examination of them has failed to detect poison in sufficient quantity to prove noxious to the organism. The sausages in these cases may simply contain the germs of decomposition and not begin to decompose until they have reached a suitable site in the intestinal canal of their host. If all sausages contained poison ready formed at the time of ingestion, it would be difficult to understand how it happens that a considerable period of time occasionally elapses before the symptoms of poisoning commence. A study of the mode of action of the various poisons that are evolved during the process of decomposition of albumens has proved of great service to the science of pharmacological physiology.

ALLEGED DEATHS FROM VACCINATION.

OUR contemporary to which we referred in last week's issue contains other letters upon this subject. A correspondent in that journal, evidently arguing upon the basis that every death occurring after vaccination may have been due to it, however indirectly, quotes among deaths from other diseases those of infants under one year of age from bronchitis, and states that the increased number of deaths registered under this heading may be due, not to alteration of nomenclature, but to a real increase in mortality from this disease, due to the lowering of the child's tender system by the vaccine disease. If vaccination is to be held responsible for such apparent increase of deaths, it is surely equally right to claim for it responsibility for the diminution in the number of deaths recorded under other headings; but the fact remains that total infantile mortality has decreased and is still decreasing, and even the thoughtful and well informed people who, this correspondent states, look upon vaccination with abhorrence, must be perplexed to find that this diminution is absolutely taking place at the same time as vaccination is supposed by anti-vaccinationists to be increasing the mortality by more than 16,000 deaths to every million births.

GASEOUS MEDICATION PER RECTUM.

THE ingestion of gaseous medicines by the lower bowel was the subject of a recent communication by M. L. Bergeon to the Paris Academy of Sciences (*Comptes Rendus*, July 12th). His research has extended to a variety of diseases, but for the present he only records his experience in the treatment of pulmonary phthisis. After having tried a variety of balsamic substances of parasiticide or antiseptic repute, M. Bergeon gave the preference to sulphurous mineral waters (Eaux Bonnes, Challes, &c.). A current of from four to five litres of carbonic acid gas traversing from 250 to 500 grammes of the sulphurous mineral water was introduced per rectum twice in the twenty-four hours. After a few days' use, cough was notably diminished and almost suppressed, the expectoration greatly modified in quality and quantity, the sweating stopped, and the general state improved; and that not only in incipient, but also in confirmed phthisis. Daily auscultation established the disappearance of moist râles.

DISEASED HORSE-FLESH IN THE MARKET.

STRANGE evidence is given in one of the daily papers to the effect that diseased horse-flesh is not uncommonly sold in London. This rumour acquires additional importance from the statement that such meat imported into the metropolis is despatched from other parts of the country in a raw state, boned, and cut in large pieces, so that it is not easily distinguished from the carcases of cattle. Reflections on such a subject are not reassuring. Not only is there an evident danger that septic disease, if present in meat of this kind, will propagate itself in domestic animals which are fed on it, but the human population are not exempt from risk, particularly since the finer shades of difference in varieties of meat are apt to be obscured by modern methods of preserving it. An inquiry into this matter should not be a tedious one, and it is evidently called for.

THE DIRECT REPRESENTATION OF THE PROFESSION.

BESIDES the issue of addresses by four candidates for the one seat in the Council for the representation of the practitioners in Ireland, and the steps for promoting Dr. Glover's election in England, no other formal proceedings have been taken. Dr. Edwin Morris, F.R.C.S. Eng., of Spalding, who years ago showed much desire for a larger recognition of the rights of Fellows and Members of his College, has intimated his willingness to stand. Other candidates for England are mentioned, but nothing is as yet certain. It is time now to expect decided steps. In Ireland there will be the embarrassment of deciding between a number of eligible candidates. Dr. Jacob's claims are very strong. His knowledge of the subjects likely to be discussed is very great, and his interest in them keen. There are two weaknesses in his position. He is not in general practice, and he is the Secretary of the Royal College of Surgeons. As regards the first objection, it is somewhat mitigated by his thorough touch of the profession. We gather that he has himself felt the force of the second disqualification, since in the last paragraph of his address he expresses his readiness to abandon the office which he now holds in the College of Surgeons. The other candidates for Ireland are Dr. Kidd, of Dublin, who is a member of the Council of the College of Surgeons of Ireland; Mr. Thomas Laffan, of Cashel, author of one of the Carmichael Prize Essays, and a practitioner of much ability and distinction; and Dr. W. K. McMordie, of Belfast. We hear as yet of no candidate in Scotland.

"SUCKING BREATH."

A SINGULAR tradition bearing on infant mortality was brought out at a recent inquest. A child aged five weeks, was found in bed suffocated beside her mother. She had been alive and awake an hour before. Death was ascribed to the presence of a cat which had got on to the bed. In support of this contention it was alleged that the animal must have lain on the infant and sucked her breath. All have noticed the tendency of cats to nestle about those to whom they are attached, as also their preference for warm corners; and these facts would appear to give colour to the idea that the cat may have lain upon the child's mouth and so smothered her. When, however, we consider that the death occurred in the early morning while the infant was with her mother in bed, that the latter was asleep, that there was a mark possibly due to pressure on the child's right cheek, and no sign that the cat had lain on the bed, it seems at least as probable that she was overlain by her own parent. "Breath-sucking" is probably a myth, or it would ere now have been proved by observation. The jury gave the only verdict possible in the circumstances—that of "Accidental death."

ATTACK ON A SANITARY CAMP.

THE Windsor urban and rural sanitary authorities, being apparently still without any permanent provision for the isolation of infectious diseases, recently erected several marquees and tents upon the Ham, Old Windsor, near the Thames. The spot is stated to be isolated, half a mile from the village, and at a considerable distance from any dwelling-house. Last week, just after a girl had been removed to the female marquee, and when only one other patient was in residence, a crowd of villagers invaded the site, threw three bell-tents into the river, and proceeded to wreck the others, attempting to set them on fire or to cast them into the water. What the exact significance in this story is we do not pretend to explain; but under any circumstances the proceedings are nothing less than barbarous on the part of the people who were engaged in it. The authorities may be to blame for not having, before this, provided a properly enclosed site with permanent buildings for the purposes of an infectious hospital; but nothing can justify the action of the mob who thus dealt with a temporary hospital which was at the time in actual occupation by sick persons. If the people were only anxious to prevent the provision of a hospital at all their ignorance is to be pitied, for it must be obvious to all sensible persons that a number of cases of infectious diseases can hardly do more harm than when they are left scattered about a district, at a number of centres where the infection would be uncontrolled.

SIR WILLIAM STOKES, OF DUBLIN.

OUR Dublin correspondent writes:—"The numerous friends of the President of the Royal College of Surgeons in Ireland will be gratified to learn that he has received the honour of knighthood at the hands of his Excellency the Lord-Lieutenant. Sir William Stokes is an able exponent of Irish surgery, a gentleman of high professional eminence, and possessed of abilities of no mean order. A clever writer, an eloquent speaker, and an honourable gentleman, Sir William holds a foremost place in professional circles in Dublin. The only regret that can be felt is that the higher dignity was not conferred upon a gentleman who holds the highest position the Fellows of the Royal College of Surgeons could bestow upon him. It cannot be denied that successive Governments have dealt very shabbily with the medical profession in Ireland, and it is to be hoped—although from the past little can be expected—that the new Government may see their way to reward the profession in Ireland as in other portions of the United Kingdom."

A FATAL CASE OF PYÆMIA FOLLOWING ALVEOLAR ABSCESS.

M. PONCET, in a communication to the *Société de Chirurgie*, relates one of those rare cases of pyæmia due to alveolar abscess. The patient, who was of intemperate habits, had been ill about ten days before admission to hospital, and showed signs of severe constitutional disturbance. Locally there was a large, non-fluctuating swelling at the angle of the jaw. The following day the outer surface of both forearms became œdematous, and large bullæ formed. Death took place forty-eight hours later. At the necropsy numerous small abscesses were found under the right side of the lower jaw, and along the upper half of the sterno-mastoid of the same side. The cellular tissue of the forearms was infiltrated with purulent matter, the spleen was pulpy, and the liver fatty and cirrhosed.

FOREIGN MEDICAL APPOINTMENTS.

DR. RONA, Assistant to the Professor of Anatomy in Breslau, has been appointed Extraordinary Professor.

Dr. F. R. von Schneider has been appointed President of the Committee of Organisation of the "International Congress for Hygiene and Demography," to be held in Vienna in 1887, and Dr. Th. von Inama Sternegg Vice-President.

Dr. Ludwig Radlkofer, Professor of Botany, has been elected Rector Magnificus of the University of Munich for the next academical year.

The Vienna professorial body having to nominate a Professor of Hygiene, has selected Professor Gruber of Graz, and Dr. Kratschmer of Vienna, each receiving the same number of votes. Some surprise is expressed in German medical circles that Professor Soyka of Prague, who is considered by many to be the greatest authority on hygiene, was not chosen; the reason given was that it was especially desirable that the professor should be a good chemist, and Professor Soyka's numerous and valuable researches on epidemiology &c. have not taken a chemical turn.

STATISTICS RELATING TO OPERATIONS ON THE KIDNEY.

DR. DAVID NEWMAN, of the Royal Infirmary, Glasgow, having collected, with a view to publication, the statistics relating to operations on the kidney for the relief of disease, is desirous of receiving from surgeons, whose operations of the kind have not been recorded, a statement of such cases. For this purpose a schedule has been prepared, a copy of which, Dr. Newman asks us to state, will be forwarded to any surgeon who may apply to him. The schedule, which contains columns headed "Diseased condition as ultimately determined" and "Results—immediate and ultimate," has already been sent to those operators whose cases have been published, in order that the records of them may be thoroughly authenticated and rendered complete.

HONOURS TO MEDICAL MEN.

ON the 30th ult. Her Majesty conferred the honour of knighthood upon the following gentlemen amongst others: Mr. John Tomes, F.R.C.S.; Mr. Douglas Maclagan, M.D.; Surgeon-General Thomas Longmore, C.B., Professor of Military Surgery at Netley; and Mr. Edward Sieveking, M.D., Physician Extraordinary to the Queen. On the 2nd inst., amongst the distinguished colonial visitors who were invested with various Orders, the following were made Companions of the Order of the Indian Empire: George Watt, M.D., and John W. Tyler, M.D.

DIVISION OF CELLS.

THE modes of multiplication of cellular elements appear to be susceptible of several kinds of classification—simple fission, gemmation, and endogenous formation, and the like; but it is probable that the essence of the process of numerical increase is the same in all the methods. Karyokinesis, the process of division of the nucleus, which usually precedes the division of the cell, generally results in the production of two nuclei and two cells. M. Cornil recently communicated a paper to the Académie des Sciences on the production of three cells by a single act of karyokinesis, in which process the nucleus was seen to become trilobate. This was not thought to be an error of observation; and M. Cornil discussed the possibility of a false interpretation of deceptive appearances.

THE EDINBURGH UNIVERSITY CLUB.

THE capping day of the Edinburgh University is a high festival to Edinburgh graduates. Even in the degenerate South the haggis goes down with an extra zest on that day. Monday last was so observed by the Edinburgh University Club and their friends at the Holborn Restaurant, who were most genially presided over by Dr. T. Graham Balfour, F.R.S. Dr. Balfour is a typical Edinburgh graduate, and the University would scarcely care to be represented by a better specimen of her *alumni*.

A VEXATIOUS ACTION AT LAW.

MEDICAL practitioners are exposed to many annoyances and beset by not a few perils; but it is seldom, happily, that members of the profession are insulted by being brought into a court of justice on pretences so utterly frivolous as that set up by a patient against Mr. S. P. Budd, of Bath, a few days ago. For a relaxed or inflamed throat, with great nervous excitability, Mr. Budd prescribed a mixture containing "bromide of potassium, carbonate of ammonia, and tincture of bark," the bromide being in the moderate quantity of some twenty-two or twenty-three grains per diem. The patient, took it into his head that the medicine did him harm rather than good, and straightway brought an action against Mr. Budd, who was put to the trouble and expense of defending the same, with the result that the jury characterised the proceedings as vexatious, and the plaintiff lost his suit. Something ought to be done to prevent the bringing of such actions as this. Would it not be possible to enact a law by which actions involving any imputation of wrong-doing by medical men—in their professional character—should be subjected to a preliminary scrutiny, such as that to which criminal charges are subjected by grand juries, before being brought into court? The injury inflicted on practitioners by absurd suits at law is not to be measured by the success or failure of the action laid.

PENNY GIFTS TO HOSPITALS AND THE COLONIAL EXHIBITION.

WE heartily remind the public of what Dr. J. A. Aveling said a few days ago in *The Times*, as to the possibility of raising a goodly sum for our needy and worthy hospitals by every visitor giving one penny to the "mechanical beggar." Over £10,000 might thus be given and never missed. Let every visitor impose this easy task on himself. The cost of our hospitals he reckons at £476,000, only £78,000 of which comes from funded property, leaving £398,000 per annum to be made up by voluntary contributions.

CORPORAL PUNISHMENT IN SCHOOLS.

IT is suggested by a correspondent signing himself "M. A. in *The Times*" that it should be a rule of custom that no magistrate should fine a teacher for undue severity, except upon the report of a medical man who has himself been at a public school, and who therefore will be able to give a just opinion upon what is right and wrong in the matter of chastisement—a qualification which many of our medical men no more possess than the parents of the Board school children." We do not know how far it would be right, or necessary, to appeal thus directly to a medical man's *personal* experiences of the birch as a standard of propriety; but we agree that the question of excess, or error, in the administration of corporal punishment in schools might very properly be submitted to medical judgment.

SUICIDES AMONG CHILDREN.

THERE can be no question that there has of late years been an increasing proportion of suicides among children, or very young persons. No psychical reason exists why this should not be so if the brain is very early put to hard labour but it is unfortunate when an organ incompletely developed is thus severely strained. The practical question is whether there may not be something in our mode of training the young which "forces" the brain unduly. Moreover, is there not a tendency to place children too soon in the career of life in a position calculated to strain and worry them?

INSECT-KILLING BOTTLES.

ATTENTION having been called to the danger to the public arising from the indiscriminate sale by naturalists and others of insect-killing bottles containing cyanide of potassium, the Registrar of the Pharmaceutical Society of Great Britain has been instructed to take immediate steps to suppress the practice, which is contrary to the provisions of the Pharmacy Act of 1858. This is a step in the right direction, and we are glad to find that action is being taken in the matter. Poisons of all kinds are sold to the public with so little restriction that anything which tends to check the practice must be regarded as a boon.

SIR B. W. FOSTER.

WITHOUT expressing any judgment on those parts of Dr. Foster's political opinions and conduct which may be supposed to have led Mr. Gladstone to move Her Majesty to confer on him the honour of knighthood, we may heartily congratulate Dr. Foster on the fact. His professional reputation will well sustain the title, and even do it credit. Dr. B. W. Foster—or, begging his pardon, Sir B. W. Foster—is too good a physician to spend his strength on unpractical politics; and we cannot altogether regret that he has been recalled to pursuits and studies more obviously worthy of his powers.

CHEMICAL HYGROMETER.

HELICES of paper coated with gelatine, and impregnated on opposite sides with substances having very different hygroscopic properties, have been employed by M. Nodon as self-registering hygrometers. It is not difficult to understand how such a coil would undergo changes of shape under the influence of alterations in the state of humidity of the circumambient atmosphere. These movements of the helix could be translated, by means of a pen of capillary tubing, on a chart moving at a definite rate. If the atmospheric humidity remained the same the pen would merely write a straight line, whilst variations in the hygroscopic state would be manifested by varying curves.

REGISTRATION OF PLUMBERS.

WE understand that the subject of brickwork and masonry has been added to the list of subjects in which examinations will be held of those who desire to possess special proof of their fitness to undertake house construction and drainage. This addition is a very proper one. While in no way desirous of detracting from the importance of the latter branch, there is much need for recollecting that it does not embrace all the conditions which are necessary to render a house healthful, and the Institute of Plumbers will be doing a public service if they gradually include in their programme every trade employed in house construction and decoration. We are glad to find that the increased number of candidates for the diploma gives good evidence that the trade is already finding its possession is of value to them.

CIRRHOSIS OF THE LIVER.

IN infants the two chief causes of cirrhosis of the liver commonly recognised are syphilis and alcoholism. It would seem strange if these were the only possible causes. A plausible theory not unsupported by facts has been advanced to the effect that the acute specific fevers may in some cases be operative in the development of hepatic cirrhosis. Interstitial changes, of the usual order, have been detected in the liver of infants who died of various acute disorders. Doubtless, in the majority of cases these interstitial infiltrations undergo resolution as the patient regains health. But there seems good reason to believe that, as M. Lauré has recently advocated, this small-celled infiltration may sometimes form the starting-point of a fibroid degeneration.

MALE NURSES.

THE Hamilton Association for providing trained male nurses is one deserving of support. It is most desirable, we think, that male nurses should be employed for attendance on the sick of their own sex whenever practicable. It is well to know that male nurses can be procured by telegraph to the "Hamilton Association, London," and that the attendants sent out will be carefully selected and well trained.

THE Austrian Minister of Education has, upon the suggestion of the professorial body of the Bohemian University of Prague, decided to establish a new clinic for children's diseases, in which the instruction will be given in Bohemian. The charge of this department will be entrusted to Dr. Neureuter, chief medical officer of the Franz Joseph Children's Hospital. The place of the deceased Professor Kaulich has been conferred on Dr. Andreas v. Hüttenbrenner, chief physician of the Caroline Children's Hospital in Vienna. The Bohemian Medical Faculty has been granted 170,000 florins for the erection of a pathological, physiological, and pharmacological institute. The building is to be commenced early next year.

THE death of Dr. Archibald Gordon, C.B., took place on Tuesday last, at West Hoathley, in the seventy-fifth year of his age. The deceased entered the Army Medical Service in 1836, and became surgeon in 1848. He was present in several actions of the Sutlej campaign in 1846, and served also in the Punjab campaign and in the Crimea. Dr. Gordon was Principal Medical Officer with the expeditionary force to China in 1857, and in the Oudh campaign in the following year. He became Inspector-General in 1867, and was placed on half-pay in 1870.

ON capping day, Principal Geddes, of the Aberdeen University, in the course of an interesting address to the young graduates, mentioned that Mr. Thomson of Pitmedden had recently given the University the sum of £3000 to found a Scholarship or Fellowship of Research in connexion with the Medical Faculty. Two or three years ago Mr. Thomson gave £6000 to found medical bursaries, so that he is indeed a liberal benefactor of the University.

IN the neighbourhood of Greussen, Thuringia, there have recently been more than sixty cases of trichinosis. Those who are most severely infected are said to have eaten pig's-meat in an uncooked state. None of the cases, however, have proved fatal. The diagnosis has been confirmed in some instances by the microscopical examination of a portion excised from the biceps muscle.

FERRYDEN, a fishing village on the Forfarshire coast, has lately been visited with a severe outbreak of typhoid fever, and Her Majesty, in expressing her sympathy with those who have suffered, trusts that an inquiry will be made into the causes of the epidemic.

AN epidemic of typhus fever has broken out on Hare Island, Skibbereen Union, co. Cork, and at the close of last week there were from forty to fifty persons out of a population of some 300 suffering from the disease. The epidemic is attributed to overcrowding.

A BATH establishment is to be added to Dr. Lassar's dermatological clinic in Berlin, where all the necessary appliances will be provided for patients at cost price.

THE death, at the age of forty-four, is announced of Dr. Hermann Maas, Professor of Surgery in Würzburg.

STURGE PRIZE COMPETITION.—Mr. George Sturge has offered to give three prizes of £25, £10, and £5 respectively to the writers of the three best essays on "The Causes of the Financial Depression in the Hospitals of London, with Suggestions for improving their Administration and Finances." The Rev. Canon Erskine Clarke, M.A., the Hon. Conrad Dillon, and Mr. J. S. Wood, will act as judges, and the successful essays will, we understand, appear in the pages of the *Philanthropist*.

THE HOSPITAL SUNDAY FUND.

On the 30th ult. a special meeting of the Council of the Hospital Sunday Fund was held at the Mansion House to receive the report of the committee of distribution, and to order payment of the awards to the various hospitals and dispensaries. The Lord Mayor presided, and among those present were Sir Sydney Waterlow, Sir E. H. Currie, Mr. Joseph Fry, Rev. Canon Nisbet, Mr. H. C. Burdett, Dr. Glover, Mr. Pitcairn, &c. Prior to the distribution of the Fund various matters were dealt with. A letter from the Rev. J. W. Bennett suggesting that the third Sunday in June should be fixed permanently for Hospital Sunday was read, and held over for future consideration. A communication was received from the Hospital Saturday Fund, complaining in effect that in making collections at theatres and workshops the Hospital Sunday Fund was overstepping its ordinary limits, and trenching upon the work of the other Fund.

Sir Sydney Waterlow said that such an objection was very foolish, seeing that both Funds were working for the same object, and that the Hospital Sunday Fund was enabled, as it dealt with larger amounts and with necessarily less complicated machinery, to make the collections at a less percentage of expenditure than the Hospital Saturday Fund.

The Lord Mayor having remarked, in regard to the collection at the theatres, that it was a spontaneous one on the part of Mr. Henry Irving, to whom the thanks of the Council were due for the help he had thus rendered, the discussion dropped.

The following resolution was then proposed and carried unanimously:—"That a special vote of thanks be sent to James Wakley, Esq., M.D., Editor of The Lancet, and member of this Council, for his second donation of £1000 to be distributed this year, and for the stimulus he has given to the metropolis by his valuable suggestions; and that cordial thanks be also recorded to Dr. Wakley and to Mr. Thomas Wakley, the proprietors of The Lancet, for the important articles and the three Special Supplements which they have caused to be published and distributed to the clergy and ministers both before and after Hospital Sunday. The Council, in passing this resolution, cannot refrain from an expression of sincere sympathy with Dr. Wakley and his family at a time when he is suffering from the severe affliction of cancer of the tongue which he is now bearing with so much fortitude."

A serious complaint was made that advantage had been taken of Hospital Sunday this year to make out-door collections and hold street processions in the West-end in aid of the Temperance Hospital and King's College Hospital. The Council strongly condemned such a movement, and expressed the hope that it would not be repeated.

The report of the Committee of Distribution stated that they recommended the payment of awards to 154 institutions, being equal in number to those which shared last year's fund, and an increase of forty-nine since the first awards were made in 1873. The following were the principal awards:—Charing-cross Hospital, £833 6*s.* 8*d.*; King's College Hospital, £1302 1*s.* 8*d.*; London Hospital, £3125; St. George's, £1979 3*s.* 4*d.*; St. Mary's, £1666 13*s.* 4*d.*; University College, £1562 10*s.*; and Westminster Hospital, £937 10*s.* The total amount available for distribution after allowing sufficiently for liabilities and the usual current expenses was £38,279, of which £36,679 was recommended for distribution among the various hospitals and dispensaries of London, and £1600—4 per cent. of the total collected—was set apart for the purchase of surgical appliances.

Sir Sidney Waterlow, in proposing "that the report of the Committee of Distribution for 1886 is hereby approved and that the several awards recommended be paid as soon as possible," congratulated the Council on the very largely increased sum placed at their disposal this year for distribution, and which had enabled them materially to augment the grants to the various institutions according to their needs and merits. They had now 50 per cent. more institutions sharing in the Fund than when it was first started in 1873. The necessity for increased help could not be too thoroughly grasped. The number of beds in the hospitals to which grants were made was 6412, but the average number occupied was only 4853. In the convalescent homes there were 2178 beds, but only 1420 were occupied for want of money. If the public could only appreciate what a great benefit their offerings afforded to the sick poor, he was sure that the Fund would be constantly and systematically helped.

Dr. Glover seconded and Sir E. Hay Currie supported the resolution, both urging that the fact of there being so many vacant beds in existing hospitals and convalescent homes should at least have the effect of preventing the starting of similar institutions until the others were overcrowded. The report was then put and carried. The following resolutions were afterwards carried: "That the cordial thanks of this Council be and are hereby given to the several members of the Committee of Distribution for the time they have so successfully given, as well as for the trouble so well bestowed in presenting the very efficient report of their proceedings"; and "that the thanks of this Council be and are hereby given (*a*) to the Right Hon. John Staples, F.S.A., Lord Mayor, for the special interest he has shown by cheerfully meeting the unusual calls that have been made upon his time and attention in this special year in connexion with the organisation of the 'Hospitals Week'; (*b*) to his Royal Highness the Duke of Cambridge, to the Marquis of Salisbury, to Sir Andrew Clark, Bart., to the Earl of Dartmouth, to the Duke of Norfolk, to the Earl of Northbrook, to the Duke of Westminster, to E. R. Cook, Esq., M.P., and to those noblemen and gentlemen who pleaded the cause of the hospitals on the several district platforms at the meetings held throughout London; (*c*) to the members of the metropolitan press who have ably advocated the cause of the hospitals, and who have fully reported the proceedings day by day through the 'Hospitals Week,' as by these efforts, combined with those of the clergy and ministers of religion, the largest sum yet received in one year has been collected in the churches and chapels of the metropolis on Hospital Sunday of 1886, the total sum received at the Mansion House in the present year to this date being £38,800."

The meeting then separated.

The total amount received up to the 3rd inst. was £38,800.

The following letter has been received by Dr. Wakley from the Lord Mayor in connexion with the first resolution passed at the above meeting:—

"Mansion-house, London, E.C., July 30th, 1886.

"My dear Sir,—I have very great pleasure in handing you the enclosed copy of resolution which has been passed unanimously this day by your colleagues on the Council, and I may add that the sincere expressions of sympathy around the table were general. Let me add my hearty congratulations on the success which has attended the movement which you inaugurated. "Faithfully yours,

"John Staples, Lord Mayor, President."

"James Wakley, Esq., M.D., &c., Editor of The Lancet, Heathlands Park, Longcross, Chertsey."

DIRECT REPRESENTATION OF THE PROFESSION: MEETING AT HIGHBURY.

THE CANDIDATURE OF DR. GLOVER.

A meeting of practitioners in the north of London and some others was held on Thursday, July 29th, at the house of Mr. Cattlin, 1, Highbury-place, to consider the desirability of selecting a candidate for the forthcoming election of direct representatives on the Medical Council. Among those present were Sir Andrew Clark, Mr. Malcolm Morris, Dr. Anderson, Mr. Nelson Hardy, Mr. Pearce Gould, Mr. Keele, Dr. Potter, Dr. Stokes, Dr. Reed, Mr. Thomas Wakley, Mr. C. H. Wade, Dr. E. H. Cree, B. G. Morison, M.B., Mr. Worley, J. J. Lough, M.B., Mr. H. F. Stokes, Dr. Williamson, Mr. W. H. Kesteven, Mr. A. Skipton, Mr. Jackson, Mr. E. Dukes, Mr. W. Cattlin, and Mr. King.

Dr. Stokes was called to the chair, and, in opening the discussion, referred to the Medical Act, and stated that the obvious intention of Parliament was that the direct representatives should be truly representative of the large body of general practitioners, members of that body themselves, and chosen by it. He thought it was important to take steps at once to recommend a candidate to the general body of the practitioners.

Mr. KEELE explained the origin of the meeting, and stated that it had been called at the request of several of the local medical men. Letters expressing regret at their unavoidable absence and concurrence in the object of the meeting had been received from Dr. Cribb, Dr. Bateman, Mr. Godfrey, Mr. Tait, Dr. G. J. Stevens, Dr. Hamilton, Mr. James Jackson, and others. Mr. Keele then read the part of the Medical Act referring to the direct representatives.

Sir ANDREW CLARK said that, although he came at the urgent request of a friend, he yet was there with all his heart. The privilege of direct representation had at last been granted. In his opinion it was wise and just, and had become necessary. He thought it morally certain that this boon was intended for those who constitute the great bulk of the profession, who do most work in it, and who are more responsible to the general public than all the consultants put together. The consultants, moreover, are already over-represented on the Council. Therefore, he hoped the general practitioners of the country would elect members of their own body. For the profession to elect consultants would be to stultify itself. He anticipated that this measure would do great good in welding into one body the entire profession, whose duties and aims are really one. But the election by such a constituency was a very difficult matter, and care, he thought, should be taken neither to elect consultants nor *dilettanti*, but only men who were in deed and truth in general practice. Then the candidates ought to be well acquainted with the recent history of the profession and known to the leading men in the profession. Lastly, it was highly important that they should be men of upright and independent character. Such men were not easy to find, but he knew one man who fulfilled all the necessary conditions, and who, if elected, would be one of the best possible members of the Medical Council—this was Dr. Glover. He knew no one more honest, upright, and independent than Dr. Glover, and he earnestly hoped that he would be elected.

Mr. NELSON HARDY fully agreed that Dr. Glover was the right man to represent the general practitioners on the Medical Council. Dr. Glover was particularly well acquainted with the work of the Council, for he had attended all its meetings for some time past, and was thoroughly familiar with the work the Council has to do. He was also sure that he would always truly represent the general body of the practitioners.

Mr. JACKSON proposed that Dr. Glover should be requested to stand.

Dr. REID seconded this resolution, which was carried most heartily. He hoped all present would do their utmost to secure Dr. Glover's election.

Mr. T. WAKLEY thought Dr. Glover was practically the man for the post. For years he had been regular in attendance upon the meetings of the Medical Council, and also at all committees of the Houses of Lords and Commons on medical matters. He was very specially indicated as the right man for the place, and it would be a pleasure to him to do anything in his power to secure Dr. Glover's election.

The resolution was carried unanimously and very heartily.

Dr. GLOVER then shortly addressed the meeting. He deeply thanked the gentlemen present. This was eminently a matter in which a man should be supported by his neighbours in the first instance, and if he could not have their support he had better not come forward. But it was very gratifying to him to see so many friends from a distance at the meeting, and he was specially grateful to Sir Andrew Clark for coming so far after a hard day's work to testify in favour of electing a genuine general practitioner. He said the Act was a very imperfect one, and even in the matter of direct representation it was not satisfactory. It enlarged an already too large Council, and the direct representatives would only be one-sixth of the Council, or five out of thirty. It was the more important, therefore, that those chosen should be chosen from the body of the profession. He would have preferred to take a little more time to think over the matter, but he was in the hands of the meeting and would be entirely guided by his friends. As it seemed the unanimous and hearty wish of the meeting, he agreed to stand.

A discussion then ensued upon the best course to be pursued to promote Dr. Glover's candidature, in which Sir Andrew Clark, Mr. Wakley, Dr. Anderson, Mr. Malcolm Morris, Dr. Stokes, Mr. Keele, Dr. Reid, Dr. Potter, Mr. Morison, and others took part. It was ultimately decided to resolve the meeting into a grand committee, with power to add to their number, and of that number a small executive committee was appointed, with Mr. Keele, Dr. Reid, and Mr. H. F. Stokes hon. secretaries. A cordial vote of thanks to Dr. Stokes was passed and suitably acknowledged, and the meeting soon after broke up.

WILLS OF MEDICAL MEN.

THE Scotch Confirmation, under seal of office of the Clerk of the Court at Aberdeen, of the trust, disposition, and settlement, with two holograph codicils, of James Milne, M.D., of Huntley, Aberdeenshire, who died on April 25th last, granted to James Watt Black, M.D., John Wilson, Robert Milne, and James Black Milne, M.B., the surviving and accepting executors nominate, was resealed in London on the 19th ult., the value of the personal estate in England and Scotland amounting to upwards of £32,000.

The will and codicil of Harvey Kimpton Owen, M.D., F.R.C.S., formerly of 20, Palace-square, and late of 60, Belvedere-road, both at Upper Norwood, who died on May 7th last, were proved on June 16th by Stamford Felce, Francis Shipston Self, and William Horsley, the executors, the value of the personal estate amounting to over £12,000. The testator bequeaths £1800 to the Royal Medical Benevolent College, Epsom, to found a scholarship to be called the "Harvey Owen" Scholarship, the conditions of which are fully set out in his will; £500 to the British Medical Benevolent Fund, of the committee of which he was for many years a member; £300 to the Society for the Widows and Orphans of Medical Men in London, of which he was vice-president; £200 to the widows' fund of the Apothecaries' Company; £100 to the distressed members' fund of the same Company; £50 each to the Lambeth Pension Society, the British Orphan Asylum, Mackenzie-park, the British Bible Society, to the minister of Gipsey-hill Church for the local charities, and to the minister of the Church of St. George-in-the-East, in which parish he was born, also for the local charities; and numerous legacies to his sister and others. The residue of his pure personal estate he leaves upon trust; £10 is to be given annually to the School Recreation Fund of the Royal Medical Benevolent College, and the remainder of the income is to be applied to the purchase of a presentation to St. Ann's or other established institution for a grandchild of one of those on the list of candidates for a pension, providing he is a medical man, or a female child of those seeking a foundation scholarship for their children. The ultimate residue of his property he gives to his sister, Miss Margaret Mary Owen.

The will of Mr. Timothy Richards Lewis, Surgeon-Major H.M. Army, late of Bywood, Woolston, near Southampton, who died on May 7th last, was proved on July 1st by the Rev. James Lewis, Mr. John Lewis, and the Rev. John Morlais Jones, the executors, the value of the personal estate amounting to nearly £4000. The testator appoints the trust funds under his marriage settlement, subject to his wife's interest, to his children equally. He bequeaths his furniture and effects to his wife, Mrs. Emily Frances Lewis; and there are a few other legacies. The residue of his real and personal estate he leaves upon trust for his wife for life, if she remains so long his widow, and then for his children.

The will of John Traill Urquhart Bremner, M.D., Inspector-General R.N., late of 4, Strand-terrace, Walmer, who died on May 8th last, was proved on July 13th by Mrs. Julia Bremner, the widow, the value of the personal estate amounting to over £2000. The testator gives all his estate and effects whatsoever and wheresoever situate to his wife.

The will of Arthur Gardiner, M.D., M.R.C.S., formerly of College-square, Belfast, late of 14, Colville-road, Bayswater, who died on April 21st last, was proved on June 21st by the Rev. John Samuel Gardiner, the son, the sole executor, the value of the personal estate exceeding £2000. The testator leaves his interest in certain house property at Dublin and Merrion upon trust for his two grandsons, Arthur Gardiner and John Stanley Gardiner; the residue of his estate he gives to his said son.

The will and two codicils of William Paton Mackay, M.D., late of the Park, Kingston-upon-Hull, who died on August 28th last, in the Island of Skye, were proved at the York District Registry on June 23rd by Alexander Russell Simpson, M.D., and Robert Russell Simpson, the acting

executors, the value of the personal estate exceeding £1000. The testator makes a provision for his father and mother, if they survive him; and subject thereto the trusts of the will are for the benefit of his wife and children.

The following legacies have recently been left to hospitals and other medical institutions:—Miss Helen Mary Covey of Castle-hill, Maidenhead, Berks, £50 each to the Brompton Consumption Hospital, the Hospital at Reading, the Bath Hospital, King's College Hospital, the National Hospital for the Paralysed and Epileptic, Queen's-square, the Royal Free Hospital, the Cancer Hospital, Brompton, the Convalescent Home at Uphill, near Weston-super-Mare, and the Maidenhead Cottage Hospital; and £25 each to the British Hospital for Incurables, Clapham-rise, and the Convalescent Home at Eastbourne.—Mr. Calvert Toulmin, of 38, Inverness-terrace, Hyde Park, £100 each to the Hospital for Sick Children, Ormond-street, the Royal Hospital for Incurables, and the British Home for Incurables.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Derby Urban District.—The vital statistics for the borough of Derby during 1885 show a birth-rate of 34·0, and a death-rate of 18 per 1000, the latter being the lowest hitherto recorded. Infant mortality, as measured by the proportion of deaths of children under one year of age to registered births, was 13·8 per cent. Amongst the sanitary work that is in progress the provision of a new infectious hospital in place of the wooden sheds originally erected during a small-pox emergency holds a prominent position. As yet the sum to be devoted to this purpose is only £4000, an amount for which it will obviously be impossible to provide the total number of beds which such a borough as Derby should regard it as necessary to possess permanently. But we hope the earliest instalment of hospital provision will include some isolation rooms for special cases. Only recently a man was removed to the existing hospital because two medical practitioners held that an eruption so far resembled small-pox that it would not be right to leave him where he then was. On the day following his removal to hospital the rash had so far developed as to show that it was not an infectious case, and the man was shortly returned to his home. Such cases must at times arise, and since patients are removed by the sanitary authorities in the interests of the public, the public should see that such accommodation is provided for their reception as will free them from the risk of contracting any other ailment in the hospital. The medical certificates received under the Local Act requiring the notification of infectious diseases were 222 in number, the actual cases thus brought under notice being 292, of which 232 were scarlet fever. Mr. Iliffe says that no difficulty arose in connexion with the Act, which was enforced without any of those drawbacks, infringements of the rights of the public, or even trespassing on the liberty of the subject or the sanctity of the confidence subsisting between medical men and their patients, which were at one time prognosticated by a few persons in the borough.

Gloucestershire Combined Sanitary Districts.—Viewing these five urban and eight rural districts as a whole, Dr. Bond is able to speak favourably of their sanitary history during 1885, the thirteenth year on which he has had to report; and it is especially noteworthy that, compared with the average of preceding years, the death-rate from zymotic diseases is low. The general death-rate from all causes stood at 15·9 per 1000. Grouping scarlatina, diphtheria, and croup together under the heading "scarlatinoid disease," it is pointed out that there is a general subsidence of a great wave of this affection which found its culmination in 1883. During 1885 the mortality had not been high, but the disease being characterised by mildness in type, a low death-rate resulted. Then, again, the bulk of the cases occurred in the early part of the year, since which there has been an abatement. One very satisfactory feature of the report is the remarkably low mortality from the group of continued fevers. In 1884 it was stated that the lowest point within the recent sanitary history of these districts had been reached as regards fever deaths, but 1885 exhibits a still further reduction of over 60 per cent. During the past year two rural districts have found themselves without hospital provision when in the face of small-pox, and as a result a serious expenditure was incurred in providing for the requirements of others than those immediately attacked, a burden which need not have been borne had the districts been provided in advance with some proper means of isolation for those actually sick. Dr. Bond refers to the beneficial result in this matter which has been brought about by pressure from the Local Government Board in securing a combination of riparian authorities on the Sharpness Canal, a place having now been provided by these for the isolation of any cholera cases, and he would wish such pressure extended to inland authorities. As regards such matters as the supervision of new buildings, slaughter-houses, bakehouses, offensive trades, &c., action necessarily varies in the different districts, but on the whole the system of sanitary administration which has been organised works well and with increasing success.

Hendon Urban District.—The death-rate for this district is the lowest Dr. Cameron has ever had to record—namely, 14·0 per 1000. The report enters into details as to the scarlatina outbreak which occurred in connexion with the use of milk from cows having a specific disease. This outbreak has been fully discussed both in connexion with Mr. Power's and Dr. Klein's reports on the whole circumstances, and in connexion with that part of it which Dr. Cameron brought under the notice of the Epidemiological Society. As regards the general sanitary administration of the district, not much that is of importance outside the localities affected is recorded. The work done and the defects remedied are shown in a tabular form; as many as 1491 houses were examined, with the result that defects were remedied when found to exist. The disposal of the sewage of the district still remains to be dealt with, since the negotiations of the authority with the Native Guano Company for the construction of precipitation works at the outfall have fallen through.

Kingston-on-Thames Urban District.—The death-rate for this borough has almost steadily fallen from 18·4 per 1000 in 1879 to 15·7 in 1885. The matter that causes most concern in connexion with the health of the district is the prevalence of diphtheria, which for the past two years had led to a death-rate largely in excess of that for England and Wales as a whole. Some parts of the borough lie on a low site, characterised by humidity of atmosphere, which is regarded by Dr. Shirtliff as tending to the production of superficial forms of ulcerated throat, affections which in turn form a suitable soil for the development of diphtheria under the influence of certain insanitary conditions. Sewer air seems to be the main condition to which diphtheria is attributed, and its influence for mischief is associated with the perversion of rain-pipes into sewer ventilators—an arrangement which is faulty from every point of view, and which more than any other tends to lead to failure at the very times when free ventilation of sewers is most needed. Whatever the cause of diphtheria, it is certain that this disease, when once present, spreads widely by personal intercommunication, and that isolation is one of the remedies which it is imperative to hold in view. The report refers to the absence of the needed infectious hospital, and it is suggested that the hospital which the rural sanitary authority have wisely determined to erect may ultimately be permitted to serve for this urban district also. A public slaughter-house is also named as one of the more prominent wants of the district.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5951 births and 3593 deaths were registered during the week ending July 31st. The annual death-rate in these towns, which had slowly increased in the preceding six weeks from 16·8 to 20·2, further rose last week to 20·6. During the first four weeks of the current quarter the death-rate in these towns averaged 19·7 per 1000, and was 1·6 below the mean rate in the corresponding periods of the ten years 1876-85. The lowest rates in these towns last week were 11·2 in Hull, 11·7 in Brighton, 14·8 in Derby, and 14·9 in Sheffield. The rates in the other towns ranged upwards to 24·7 in Preston, 25·5 in Norwich, 26·9 in Cardiff, and 31·0

in Leicester. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had steadily increased in the preceding seven weeks, under the influence of the mortality from infantile summer diarrhœa, from 263 to 754, further rose last week to 872; they included 646 from diarrhœa, 83 from measles, 59 from whooping-cough, 39 from "fever" (principally enteric), 23 from scarlet fever, 22 from diphtheria, and not one from small-pox. The lowest death-rates from these zymotic diseases were recorded last week in Hull, Oldham, and Huddersfield; and the highest in Birkenhead, Norwich, and Leicester. The mortality from diarrhœa showed a further general increase, the largest excess being recorded in Cardiff, London, Birkenhead, Norwich, and Leicester. Measles caused the highest death-rates in Halifax, Birkenhead, and Preston, whooping-cough in Preston, and "fever" in Cardiff and Portsmouth. Small-pox caused no death either in London and its outer ring or in any of the twenty-seven large provincial towns. The number of small-pox patients in the metropolitan hospitals situated in and around London, which had been 13 and 11 on the preceding two Saturdays, had further declined to 10 at the end of last week; 1 case was admitted to these hospitals during the week, against 3 and 2 in the previous two weeks. The deaths referred to diseases of the respiratory organs in London, which had declined in the preceding four weeks from 197 to 162, were last week 172, and 18 below the corrected average. The causes of 71, or 2·0 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Salford, Leicester, Brighton, Bolton, and in six other smaller towns. The largest proportions of uncertified deaths were registered in Sheffield, Oldham, and Bristol.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 19·1, 19·2, and 19·8 per 1000 in the preceding three weeks, declined again to 19·5 in the week ending July 31st; this rate was 1·1 below the mean rate during the same week in the twenty-eight English towns. The rates in the Scotch towns last week ranged from 14·6 in Greenock and 15·6 in Paisley, to 21·2 in Edinburgh and in Aberdeen. The 481 deaths in the eight towns showed a decline of 8 from the number in the previous week, and included 34 which were referred to diarrhœa, 18 to whooping-cough, 8 to measles, 4 to scarlet fever, 2 to diphtheria, 1 to "fever" (typhus, enteric, or simple), and not one to small-pox; in all, 67 deaths resulted from these principal zymotic diseases, against 68 and 65 in the preceding two weeks. These 67 deaths were equal to an annual rate of 2·7 per 1000, which was 2·3 below the mean rate from the same diseases in the twenty-eight English towns. The deaths referred to diarrhœa, which had increased in the preceding six weeks from 8 to 33, further rose last week to 34, of which 15 occurred in Glasgow, 7 in Edinburgh, and 6 in Dundee. The annual death-rate from diarrhœa in these Scotch towns last week did not, however, average more than 1·4 per 1000, whereas the mean rate from the same cause in the twenty-eight English towns was 3·7. The 18 fatal cases of whooping-cough corresponded with the number in each of the previous two weeks, and included 13 in Glasgow and 2 in Perth. The 8 deaths from measles showed an increase of 5 upon the number in the previous week, and included 4 in Edinburgh, 2 in Glasgow, and 2 in Leith. Three of the 4 fatal cases of scarlet fever occurred in Glasgow, and the single death from "fever" in Paisley. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had declined in the preceding six weeks from 93 to 67, further fell last week to 63, but exceeded the low number in the corresponding week of last year by 8. The causes of 67, or nearly 14 per cent., of the deaths in the eight towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 19·7 and 21·0 per 1000 in the preceding two weeks, declined to 17·3 in the week ending July 31st. During the first four weeks of the current quarter the death-rate in the city averaged 20·3; the mean rate during the same period was 21·0 in London and 19·2 in Edinburgh. The 117 deaths in Dublin last week showed a decline of 25 from the number in the previous week, and included 2 which were referred to scarlet fever, 1 to diphtheria, 1 to "fever," 1 to diarrhœa, and not one to small-pox, measles, or whooping-cough. These 5 deaths from the principal zymotic diseases showed a considerable decline from the numbers in recent weeks, and were equal to an annual rate of 0·7 per 1000, the rates from the same diseases being 0·7 in London and 2·7 in Edinburgh. The 2 deaths from scarlet fever showed a slight increase upon the numbers in the preceding two weeks, whereas the fatal cases of each of the other zymotic diseases (including diarrhœa) had declined. Three inquest cases and 3 deaths from violence were registered; and 32, or nearly one-third of the deaths, were recorded in public institutions. The deaths of infants, as well as those of elderly persons, showed a considerable decline from the numbers returned in the previous week. The causes of 20, or more than 17 per cent., of the deaths registered during the week were not certified.

THE SERVICES.

INDIA OFFICE.—Brigade Surgeon G. Farrel, of the Indian Medical Department, has been appointed Principal Medical Officer to the troops in Upper Burmah.

ADMIRALTY.—The following appointments have been made:—Surgeon Arthur W. May, to the Portsmouth division of Royal Marines; and Surgeon James O. B. Williams, to the *Jackal*, for temporary service.

ENGINEER VOLUNTEERS.—1st Cheshire: Hugh Miller, M.D., to be Surgeon.

RIFLE VOLUNTEERS.—1st Volunteer Battalion, the Buffs (East Kent Regiment): Surgeon and Honorary Surgeon-Major C. Holttum resigns his commission; also is permitted to retain his rank, and to continue to wear the uniform of the battalion on his retirement. Philip Phelps, Gent., to be Acting Surgeon.—2nd Perthshire (the Perthshire Highland): John Allan, Gent., M.B., to be Acting Surgeon.—2nd Volunteer Battalion, the Worcestershire Regiment: Captain Joseph Randle Buck is appointed Surgeon.

"Audi alteram partem."

CLOSURE OF LOCK HOSPITALS IN INDIA.

To the Editor of THE LANCET.

SIR,—A little over a year ago it was announced that the Government of India had decided to close several lock hospitals as an experimental measure, and in the North-West Provinces four were selected and closed during the year 1885. Immediately after this order appeared I drew attention to it in your columns, and predicted that the inevitable result would be an enormous increase in disease among our European troops. The stations selected were Allahabad, Cawnpore, Meerut, and Chakrata. The result is now before the public in the annual report of the Government of the North-West Provinces to the Government of India, and how true my forebodings were is only too evident.

The following *verbatim* extracts from the report in question will speak for themselves:—Paragraph 3: "In 1885 the lock hospitals at four important military stations were closed; but a careful record of disease was maintained for comparison with stations in which the former system was maintained. The result is undoubtedly to show an enormous increase of disease. The ratio of hospital admissions rose in Allahabad from 260 to 850 per 1000; in Cawnpore from 166 to 309; in Meerut from 328 to 472; and in Chakrata from 123 to 244."

This is bad enough, but it is not the worst part of the tale, as in all the neighbouring stations disease increased in an unprecedented manner—a fact which may fairly be attributed to the migration of diseased women, who infected the men, and through the men the registered women in protected places. "In Agra the rate of admissions per 1000 rose from 223 to 416; in Bareilly, from 228 to 485; in Moradabad, from 424 to 972 (in this station the lock hospital was temporarily closed during the absence

of troops, so that on their return the registered and unregistered women were much diseased); and in Naini Tal, from 196 to 304. In only three stations, Jhansi, Muttra, and Fatehgarh, were the results better than in the previous year."

The Sanitary Commissioner in his report to the Government of the North-West Provinces characterises the results of the experiment at Allahabad as "lamentable," at Cawnpore as "very unsatisfactory," at Meerut the same remark applies, and at Chakrata as "fairly satisfactory," though the ratio of admissions at this station rose from 123 to 244 per 1000! The Lieutenant-Governor's report concludes by saying: "The results of the year give occasion for considerable concern, and already indicate a doubt (!) whether the system of cantonment lock hospitals can be relaxed or abandoned without a serious increase to service-incapacity in the troops. Further experience, however, is required to warrant the condemnation of the experiment made last year." With reference to these remarks I will again quote the Sanitary Commissioner's report, paragraph 81: "Its figures are such as have never before fallen to my lot to record, in all this series of twelve reports. As regards the garrison generally, they witness to the unprecedented ratio of 346·3 admissions to hospital per 1000 of strength, for comparison with 224·9 in 1884. As regards the garrison of the four stations of abolished management, they witness to a mean admission ratio of 463·4, for comparison with 218·8 in 1884. . . . Viewed in any possible light, the figures present proof of most unsatisfactory result."

Now for a few facts. During the year 1885, no fewer than 1950 diseased women were admitted and treated in the lock hospitals that remained open, at a total cost of 28,833 rupees, or, at the present rate of exchange, considerably less than £2000; out of which sum, however, the Government paid only 2889 rupees, or under £200, the remainder having come from the cantonment funds—the sale of grass, wood, letting of land for grazing, tillage, &c. Out of about 11,000 men 4002 were admitted for venereal disease, and, putting the average of each man at twenty days in hospital, and charging one shilling a day for his maintenance, medical attendance, &c., we have an actual money loss to the State of over £4000, to say nothing of the indirect loss caused by deaths and invaliding, the result of disease. In this garrison we may take it that, on an average, one company of men are constantly off duty, suffering from venereal disease, and when this is multiplied by the remainder of the Indian garrison, the enormous amount of inefficiency from this cause will be apparent. We hold India by the sword, and the health of every unit of the army is a matter of such extreme importance to the State that it appears simply suicidal to attempt to repeal laws that were doing so much good. It is not difficult to foretell the result of any further experiments in the same direction; but it would appear that "Quem Deus vult perdere, prius dementat" is as applicable as ever, and to none more so than the advisers of the Government of India.—I am, Sir, yours obediently,

J. B. HAMILTON, M.D.,
Station Hospital, Lucknow, Brigade-Surgeon, Med. Staff.
July, 1886.

THE PECULIAR PEOPLE.

To the Editor of THE LANCET.

SIR,—In your issue of to-day's date I notice under the above heading a criticism of the evidence given by me at an inquest on the body of a child who had died without medical attendance. At the post-mortem I found a caseous mass in the left lung, with general tuberculosis of lungs, liver, spleen, intestines, &c. There was also tubercular meningitis, which was the immediate cause of death. Under these circumstances I was certainly unable to swear that life would *positively* have been prolonged by medical treatment, and the coroner, in the absence of such evidence, most properly directed the jury not to return a verdict of manslaughter. Whether medical attendance during measles and the subsequent broncho-pneumonia would have prevented the caseation of the lung is doubtful, and if all parents of children of the lower orders are to be deemed criminals for not calling in a doctor in measles our prison accommodation will soon be insufficient. The law on these cases was distinctly laid down in R. *v.* Morbey (8, Q.B.D., 571), as follows:—"Mere neglect on the part of a parent to provide medical aid for his child of tender years, in consequence of which his child dies, is not manslaughter, unless it is proved *affirmatively* that the death was caused or accelerated by such neglect; and medical evidence on behalf of the prosecution that the child's life *probably* might have been prolonged or saved by the parent calling in medical aid is not sufficient evidence to support a conviction" (Harris on Crimes). Such, right or wrong, is the law, and I maintain, Sir, that a verdict of manslaughter in this case was not warranted by the facts, and would have been promptly quashed by the judge at the Central Criminal Court. As I think the comment on myself rather unfair, I must ask you to insert this in your next issue.—I am, your obedient servant,

C. LLOYD JONES, M.A., M.D., Barrister-at-Law.
Blackfriars-road, S.E., July 31st, 1886.

ASSOCIATION OF MEMBERS OF THE ROYAL COLLEGE OF SURGEONS.

To the Editor of THE LANCET.

SIR,—Will you allow me, through the medium of THE LANCET, to inform Members of the Royal College of Surgeons of England, that the petition prepared by the Association of Members of the College (and which has been already extensively signed) will lie upon the table of the entrance hall Pavilion, Brighton, during the time of the meeting of the British Medical Association. All Members who have not yet signed are earnestly requested to do so. If possible, a meeting of the Members of the College will be arranged for Wednesday next.—I am, Sir, yours &c.,

JOSEPH SMITH,
A Vice-President of the Association of Members of the Royal College of Surgeons of England.
Thornton-avenue, Streatham-hill, Aug. 5th, 1886.

EDINBURGH.

(*From our own Correspondent.*)

UNIVERSITY GRADUATION CEREMONIAL.

THE Annual Graduation Ceremonial in Medicine, Law, and Divinity took place in the United Presbyterian Synod Hall on Monday, Aug. 2nd. As is usually the case, the graduates in medicine far outnumbered those of other faculties, and reached a number never attained in former years, since 219 gentlemen were promoted to the degrees of M.B. and C.M., and 49 to that of M.D. A number of honorary degrees were at the same time conferred; amongst them that of LL.D. was bestowed upon Professor Tarnier of Paris, who met with a most enthusiastic reception upon his presentation for the degree. Lord Inglis, the Chancellor of the University, presided, and performed the ceremony of "capping" the graduates—a part of the proceedings which was this year unusually protracted. The customary graduation address was delivered by Professor John Chiene, of the chair of Systematic Surgery. His speech dealt chiefly with topics of local interests and contained suggestions of a valuable nature tending to the further development and increased prosperity of the Edinburgh school. More especially he urged the claims of post-graduate instruction and of hospital extension, and in regard to the latter he appealed with telling force to the inhabitants of Edinburgh, showing clearly how much the city owes to the existence of its great medical school, how it could be best maintained in its present prosperous condition, and the opportunity it offered for still further advances in the efficiency of its system of training by the provision of increased facilities for practical instruction. This appeal was accompanied by a short summary of the details of a plan by which the accommodation for hospital patients can be raised to a total strength of 1000 beds. The particulars of the plan do not involve any great alterations, and would seem in many respects to have been allowed for as distant possibilities when the present hospital was designed in 1869. They are rather of the nature of a completion than of a modification of original intentions; and, considering the immense boon which they would prove to patients, to teachers, and to taught, it is to be hoped that the £60,000, which Professor Chiene estimates they will cost, may be soon forthcoming. Professor Chiene reviewed also in his address the present

arrangements for clinical examinations in Edinburgh, and advocated the formation of joint boards of examiners in clinical medicine and surgery in connexion with the university and corporations' final examinations, so that by this means all the available hospital material might be freely drawn upon for the purposes of each, and a system of cordial reciprocity thus established between the two forces which constitute the Edinburgh school.

Edinburgh, Aug. 3rd.

BELFAST.

(From our own Correspondent.)

THE CHAIR OF SURGERY IN QUEEN'S COLLEGE.

ALTHOUGH there has been no public notification that Dr. Gordon has resigned the Professorship of Surgery in Queen's College, which he has so worthily filled since 1849, it seems to be generally understood that he will not again lecture, and already there is considerable discussion, as well as speculation, in medical circles as to his probable successor. Three canditates are in the field—Dr. J. Walton Browne, Mr. John Fagan, and Dr. Thos. Sinclair. Dr. Browne (son of Dr. Samuel Browne) is senior surgeon to the Royal Hospital, and surgeon to the Belfast Ophthalmic Hospital, and at both of these institutions he has for a long time been a clinical teacher. He is an ex-president of the Ulster Medical Society, and holds the degrees of B.A. and M.D. of the Queen's University; and he is also a member of the Royal College of Surgeons of England. He became qualified in 1867. Mr. John Fagan is a surgeon at the Royal Hospital and surgeon to the Belfast Hospital for Sick Children (an appointment which he has held since the foundation of the hospital in 1873), and at both places he has taught classes of students. He was president of the Ulster Medical Society last year, and is now president of the North of Ireland Branch of the British Medical Association. He became qualified in 1866, and is a Fellow of the Royal College of Surgeons of Ireland. Dr. Thos. Sinclair is surgeon to the Ulster Hospital for Children, and assistant-surgeon to the Royal Hospital. When Dr. Anderson was appointed professor of natural history at Galway, Dr. Sinclair succeeded him as demonstrator of anatomy at Queen's College. He is an M.D. and M.Ch. of the Queen's University, and is a Fellow of the Royal College of Surgeons of England. He qualified in 1881. Two documents have already been sent to members of the profession here asking them, in the one case, to sign a testimonial to the President of the College in favour of Dr. Sinclair, and, in the other, to sign a memorial to the Lord-Lieutenant of Ireland on behalf of Dr. Walton Browne. It is said also that a number of the students have framed a petition in favour of Dr. Sinclair's appointment. The duties of the chair consist in giving a systematic course of lectures on the theory and practice of surgery, and in conducting a class of operative surgery. It is a winter lectureship. The appointment rests with the Lord-Lieutenant, who sends the applications and testimonials to the President of the College, asking his opinion, and, as a rule, his nomination is accepted.

Belfast, Aug. 3rd.

PARIS.

(From our own Correspondent.)

TINEA IN FRANCE.

A PROPOSITION has been made at the Paris Municipal Council by Dr. Robinet, one of its members, to the effect that, considering that children affected with tinea in its various forms are treated in the general hospitals, where they are not even separated from the other patients, and where consequently they themselves are liable to contract the contagious maladies prevalent in these hospitals (diphtheria, measles, scarlet fever, variola, whooping-cough, &c.), and considering also that the hospitals for children are overcrowded, it is expedient that a separate hospital should be established for the treatment of the class of skin diseases above named. This arrangement will have the advantage of preventing the spread of the disease in question, and will leave more beds available in the general hospitals for other diseases. To give your readers an idea of the great prevalence of tinea in this country, I may mention that at a recent meeting of the Academy of Medicine, Dr. Feulard furnished the following statistics concerning favus among conscripts. From 1873 to 1885, 3872 men were rejected by the examining board on account of their being affected by that disease. The departments which furnished the most of these cases are Pas-de-Calais, Nord, Aveyron, Tarn, Herault, Landes, Seine-Inférieure, and Côtes-du-Nord. These departments constitute three distinct geographical groups, north, west, and south. These results are the same as those obtained by M. Bergeron, who made similar researches in 1865. From 1841 to 1849 M. Bergeron recorded 730 annual exemptions from favus. At that period a comparatively small number of men were examined. From 1850 to 1860, the yearly average was estimated at 438 men affected with favus out of the total number examined, but the real number would be much higher, being estimated at 800. From 1873 to 1885, the yearly average is stated to have been 300, thereby showing a decrease of more than half in the number of exemptions from this cause. A more regular and exact inspection of schools and the isolation of persons suffering from favus are considered to be the best means of preventing the extension of the disease among the population.

M. CHEVREUL.

In anticipation of the 100th birthday of M. Chevreul, the venerable Academician, which occurs on the 31st of this month, a series of fêtes have already commenced. A banquet was given on Saturday last, in the Latin quarter, by the students of the University, in honour of him whom they styled their "doyen," or the senior student. Great preparations are being made for a grand *fête de nuit* in the garden of the Luxembourg Palace, to which present and former students, with others who have been invited, will alone be admitted.

ORGANISATION OF HOSPITALS.

M. Paul Aubry, hospital externe, member of the Society of Commercial Geography of Paris, is charged with a mission to Athens, Constantinople, Broussa, Smyrna, Magnesia, Alexandria, and Cairo, to study the organisation of hospitals in these different cities, particularly as regards the treatment of leprosy and mental alienation.

M. PASTEUR.

Rumours have been circulated that M. Pasteur is lying dangerously ill from an attack of general paralysis. On making inquiry at his residence, I learned that the report was false. The eminent biologist is at present at his country villa, where he is enjoying peace and quiet, and is in tolerably good health.

HYDROPHOBIA AMONG CAMELS.

Several cases of hydrophobia are reported to have occurred among camels at Hezeilat (Algiers). It is stated that a few months ago two camels were affected by the disease, and died in thirty-six hours without presenting any trace of a bite. It is supposed that the disease was imported by a rabid horse which had during the night joined the herd. The propagation of the disease is attributed to the saliva which the rabid animals left on the pasturage, which saliva was probably absorbed by the sores in the mouth to which camels are frequently subject. The military authorities have interdicted for three months grazing on the pasturage in which the contaminated herds were enclosed.

DEATH OF DR. ESTOR.

Dr. Estor, Professor of Pathological Anatomy and Histology at the Faculty of Medicine at Montpellier, died suddenly, at the age of fifty-six, of disease of the liver.

Paris, August 3rd.

EGYPT.

(From our own Correspondent.)

FEVER EPIDEMIC AT TOURAH CONVICT PRISON.

REFERENCE has already been made to an epidemic of relapsing and typhus fevers which broke out at this prison last April, and, now that it is all ended it is fair to give a more detailed account of it. The prison cells, which were originally constructed to hold 648 convicts by night have been greatly overcrowded this year, owing to the want of

sufficient prison accommodation in Egypt. During January and February the inmates averaged 955, and in March this excess rose to 1014. During the first week of April 120 convicts suffering from "fever" were admitted from the prison cells into a temporary hospital in the building, and a second native doctor, a dispenser, and some hospital necessaries were sent from Cairo to assist the overworked prison doctor. The prison is near a station on the Helonan Railway, about eight miles from Cairo, and has the advantage of being a few yards from the Nile and of being surrounded by very pure desert air. Two medical commissions, one entirely composed of natives, visited the epidemic, but, owing partly to the temporary absence of the English heads of the prison and sanitary departments, no satisfactory action was taken until May 14th, when the whole of the sick were officially placed under the charge of Dr. Milton, Director of Egyptian Hospitals, and the prison officials received orders to carry out any instructions given by the Sanitary Department. The state of affairs was then found to be as follows: 214 deaths had occurred during the six weeks ending May 15th, as compared with 34 during the previous six weeks, the total number of convicts thus being reduced to 760, of whom more than 200 were in hospital or sickening of fever. Many of the healthy men, the able-bodied of whom were working in stone quarries for eight hours a day, looked weak, thin, and anæmic, and both healthy and sick were unwashed and covered with lice, while no arrangement for washing existed in the establishment. No necropsies had been made, no notes or temperatures taken, very little medicine or stimulants administered, and neither of the native doctors in charge could throw much light upon the diagnosis of the patients. These were mostly lying on prison mats on the floor, and were fed on coarse native bread, and very little vegetables, with meat broth, and they were unprovided with conservancy arrangements. The work for the first few days consisted in diagnosing, classifying, and treating the sick, establishing a bath and special kitchen, issuing clean clothes, supplying beds, milk, brandy, and nourishing food, performing necropsies, and providing tents for convalescent patients as discharged from hospital. As preventive measures, the healthy were washed in the Nile, extra food, including meat, was served out to them, clean clothing provided, and the period of work reduced to three hours per day. The sanitary authorities also recommended roof ventilation to be immediately provided in the cells, but this was not at once carried out. The cells, originally built for 648 men, for eleven hours per diem, provided cubic space varying from 293 to 311 feet per man, and this was of course further reduced when the number of inmates was increased. The ventilation also was most deficient, and the conservancy arrangements very unsatisfactory. The hospital cases, roughly speaking, were found to be one-half relapsing fever, one-sixth typhus, one-sixth diarrhœa and dysentery, and the remainder lung and other diseases. Volunteers from the healthy were chosen to nurse the sick, and some of them contracted relapsing but not typhus fever. Many of the prison officials, from the governor to the warders, also suffered from relapsing fever. The deaths for the six weeks, commencing May 16th, were only about 77, and at the end of that time the epidemic was practically ended, only a few relapsing, convalescent, and diarrhœa cases remaining. In June, a Committee of Inquiry, consisting of a colonel and two surgeon-majors of the Army of Occupation, was appointed by the Egyptian Government, and their voluminous report has now been forwarded to the English Government. No cases of fever spread from the prison among the neighbouring villagers, and this immunity has been noticed in previous similar epidemics in Egyptian villages.

ENGLISH HOSPITAL AT RAMLEH.

The military hospital for the troops at Alexandria is situated on a cliff of the seashore, and forms part of the Mustapha Pasha Palace. The palace was burnt down in Ismail's reign and rebuilt in 1872, the foundations being partly taken from some well-preserved ruins of a Roman camp in the neighbourhood. In spite of its modern construction, the lath and plaster are everywhere decaying, and occasionally a whole ceiling falls. The maximum number of beds is 415, but this includes at least 100 in badly-ventilated corridors, which are only used when absolute pressure requires. Fifteen hundred cubic feet are allowed for each patient, and 2000 for enteric cases, which are kept in a separate wing of the hospital. The ventilation is perfect in most of the wards, a deliciously cool air blowing straight from the sea. The dry-earth system is of course used throughout the hospital and barracks, the stools, when disinfected, being taken out to sea. The total strength to-day in Alexandria is 2200, of whom 278 are on the sick list, and 56 are suffering from enteric fever. This gives a present sick rate of 12·6 per cent., and an enteric rate of 2·5. In 1883, the Alexandria returns for the year gave 10·9 sick rate, and 4·1 enteric; in 1884, sick rate 9·3, and enteric 5·3; in 1885, sick rate 8·4, and enteric 5·1. It should be mentioned that the four months from April to July are the worst months for enteric fever in Alexandria. An interesting case in the hospital lately will be reported in detail by the medical officers in charge. An English soldier, aged twenty-four, was in hospital for simple continued fever, and was thought to be doing well, when jaundice and other bad symptoms appeared, and he died three days after of acute atrophy of the liver. This disease is as rare in Egypt as in England.

ANNUAL REPORT OF THE GERMAN HOSPITAL.

The Victoria Hospital at Cairo, nursed and managed by the deaconesses of Kaiserswerth, has just issued its first report. The building was constructed at a cost of £5300 on land given by the Egyptian Government, and was opened for the reception of patients in January, 1885. During the year 186 inmates of twenty different nationalities and no less than seven religious beliefs were received. First-class patients pay 10s. a day, second-class 6s., and the lowest class 2s. 6d. 2061 out-patients have also been treated during nine months of the year, but this number is far exceeded by those who now attend at the native hospital.

Cairo, July 21th.

Obituary.

WALTER MOXON, M.D. LOND., F.R.C.P.

THE death of Dr. Moxon leaves a gap in the ranks of the profession which it will be difficult to fill; not that there is any lack of good physicians, but because the physician in him showed only one side of a mind that exerted an extraordinary influence through the variety of its sympathies. That he was a physician of the highest type, well versed in literature, acute in observation, exact in diagnosis, and rational in treatment, all will be ready to admit; but when all the qualities that are essential to a great physician have been enumerated, and it is allowed that he possessed them in the highest degree, the picture fails to show in what his power lay; for Moxon's was a many-sided intellect, and this induced men of every profession to think him best suited for the one to which they themselves belonged. Barristers envied his rapidity of thought, fertility in argument, and fluency of speech; men of science were struck by his perseverance, his industry, and his immense power of grasping details; dignitaries of the church, if sometimes slightly alarmed by the breadth of his views, recognised that his fervour and gift of persuasion might exert influence from the pulpit, and would have had him ordained. Yet no one could say that Moxon was lost in the medical profession; perhaps no other would have allowed such free play for so fresh and vigorous a mind.

One of a large family, each individual of which has shown exceptional talent, Walter Moxon was born on June 27th, 1836, at Midleton, co. Cork, and was just fifty years of age at the time of his death. His father was in the Civil Service, and, migrating to London, became Chief Accountant of Inland Revenue, and one of the original founders of the co-operative system of trading. His mother was a fair maid of Kent, a lady of tender heart, strong faith, and true virtue, who by her gentle teaching and loving nature exerted a powerful and lasting influence over her family. To this son her memory was in itself a religion. He frequently visited her tomb; and at the last, when broken down in health and under strong presentiment of his approaching end, his steps were again directed towards her

grave. Through his father he was distantly connected with Edward Jenner, the discoverer of vaccination, and one of the family bore his name.

Walter Moxon was educated at a private school, and at an early age was placed in a merchant's office in the city of London. But commercial pursuits proved to be little in accord with his refined tastes and generous nature: an imperious demand on the part of the principal excited a rebellious retort from the apprentice, which quickly terminated the engagement. Having now determined to enter the medical profession, he set himself to pass the difficult matriculation examination of the University of London, and this he accomplished without the assistance of a tutor. He entered as a student at Guy's Hospital in 1854, and soon attracted the attention of his teachers by the accuracy of his work and his exactness in points of detail. Among his fellow-students was Mr. Arthur Durham, with whom there existed a friendly rivalry for a position on the staff, to which each eventually attained. At the first M.B. examination of the University of London, which he passed in 1857, he was placed first in honours with an exhibition and a gold medal in materia medica, and second in honours with a gold medal in chemistry. In the following year, before graduation, he was appointed Demonstrator of Anatomy in the Medical School. This appointment, he always maintained, lowered his position at the second M.B., which he passed in 1859. Although he gained no exhibition at this examination, he took honours in every subject. He graduated M.D. in 1864, and was elected a Fellow of the Royal College of Physicians in 1868.

Moxon's faculty for teaching became at once apparent when he was appointed Demonstrator of Anatomy. The students crowded round him the moment he entered the dissecting-room, to be amused and instructed at the same time. His knowledge of the human frame was exact and complete; but it was not his habit to teach mere book anatomy, for he used to say, "The books have better memories than you have, and will beat you." His plan was rather so to interest his pupils as to make them search for themselves. An excellent draughtsman and a neat dissector, he possessed every qualification for the post, which he held for a period of five years. At this time the exigencies of examinations had not levelled the junior teachers to the grade of crammers, but left them plenty of time for original scientific investigation. Of this spare time Moxon made good use. He became a Fellow of the Linnæan Society, and devoted himself to microscopic research. In 1864 he read before this Society a paper on "New Points in the Anatomy of the Rotatoria," in which he described some heretofore unnoticed "cilium funnels" in the water vascular system. Leaving the dissecting-room in 1864, on being appointed assistant-physician, he became Lecturer on Zoology and Comparative Anatomy, and continued to work assiduously at the microscope. In 1866, in the *Journal of Microscopic Science*, he published a paper on the "Peripheral Termination of Motor Nerve, showing the direct ending of Nerve on Muscle," wherein for the first time in this country was described the disc-like termination of the axis cylinder within the sarcolemma. A paper on the "Anatomy and Mode of Division of the Stentor and other Infusoria" appeared in the *Journal of Anatomy and Physiology* in 1869. Following Dr. Wilks as Lecturer and Demonstrator of Pathology, with charge of the museum, he threw himself with zeal into this new department; and the Pathological Society's Transactions show what labour and care he bestowed on his post-mortem examinations. He designed a book in which is kept an accurate record of every examination made by him—a marvellous piece of work, in which the kind of disease in each organ is indicated by a dash of colour that at once strikes the eye. About this time, on account of the health of his wife, he took a house at Hornsey, and he used to go home laden with pathological specimens for microscopic examination, at which he would work late at night and in early morning. Some of his best work was done at this time, notably a magnificent and unique series of pathological drawings, which are preserved in the post-mortem theatre at Guy's Hospital, and are well worth inspection. Whilst holding the chair of Pathology he undertook to re-edit Dr. Wilks' "Lectures on Pathological Anatomy." For the editing of an original work it is well to choose a man with no originality; then a book may pass through many editions unchanged. Moxon could not re-edit—he completely transformed the work; but the volume published under the joint names of Wilks and Moxon remains the representative English work on Pathology. He also published a series of "Lectures on Analytical Pathology," which served to increase his reputation as an original thinker and exact pathologist. On leaving the pathological department, he was appointed Lecturer on Materia Medica and Therapeutics. This course of lectures, which is generally looked upon with dread by the student, in his hands became the most popular in the hospital. No subject could more severely test a lecturer's power. Entering the theatre without a note, he kept his class amused and instructed from the beginning to the end of the lecture. He held his audience absolutely and imperiously under his control, never allowing so much as a whisper until he had finished speaking. Men of all years flocked to these lectures, not merely for instruction in the subject of his discourse, but to secure for themselves an intellectual treat; in this they were never disappointed. But not as a lecturer only did Moxon lay claim to be considered an exceptional teacher. His clinical instruction was equally fascinating: whilst leaving no sign unnoticed, no symptom uninterpreted or undiscussed, he kept up a flow of sparkling dialogue full of suggestions for after-reflection. In this way the germs he distributed often grew and bore fruit in the minds of his pupils, and many scientific papers may be traced to his initiative. His ideas on the importance of clinical observation may be gained from the following extract: "Knowledge of facts got by reading is practically worth nothing. The only use of books is to instruct you in the meaning of a name, your own eyes and ears and touch must teach you the nature of the thing." On the retirement of Dr. Owen Rees, Moxon succeeded as physician to Guy's Hospital; he then began to devote himself still more to clinical instruction. About five years ago he became Lecturer on Medicine, and this chair he continued to hold until the time of his death. On the preparation of these lectures he bestowed much labour, but he never hampered himself with a note, so that the delivery always appeared to be spontaneous. Given entirely without theatrical effect, they compelled attention and charmed at the same time by the brilliancy of thought, the epigrammatic sayings, and the pointed illustrations distributed through them. Never dull, and acutely sensitive to the impression conveyed to his hearers, he never lost touch of his audience, but drew them insensibly after him. His oratory was of a persuasive, argumentative kind, tending towards metaphysical thought, abruptly broken by some sudden surprise or unexpected witticism to carry his audience back to the major premiss, or to assist them in anticipating his conclusion. His hearers quickened their ears and hung upon his lips

> "When some chromatic sequence of fine thought
> In learned modulation phrased itself
> To an unconjectured harmony of truth."

All were interested and amused, even if they left by their own fault uninstructed or unconvinced.

Dr. Moxon's contributions to the literature of his profession were numerous and valuable. Whatever he touched he cast a glow of original light upon, and, as a colleague remarked, "he never fell to the level of anything commonplace." To scientific minds those papers will present the greatest interest wherein he was fettered by rigid facts, so that his mental activity found exercise only in elaborating details. But where there was left room for speculative thought, his fertile imagination winged itself from point to point with a touch as light as that which in gathering sweetness scatters wide the anther-dust. It was then that he raised men's thoughts to an ethereal height and strained their eyes towards the vanishing point. He carried you without effort through the deepest labyrinths of metaphysical thought to an inquiry into the origin of things, subtilely following his silken thread till he landed you at the inconceivable, and then, with a remarkable dexterity, he would bring you back as from a dream to awaken into ordinary daylight. When unconstrained by subjection to everyday facts, as in giving addresses or introductory lectures, he simply revelled in illustration and anecdote, sometimes to such an extent as to obscure his main argument; but those who listened never wore a look of weariness, and went away refreshed and enlightened. His sketch of the life and professional career of his colleague, Dr. Hilton Fagge, was a remarkable production. It appeared in THE LANCET, Aug. 30th, 1884. In this article Fagge became the text of a Moxonian homily. The picture was scarcely that of Fagge as we remem-

bered him, but Fagge refracted through Moxon's intellectual prism. Moxon's unpublished "Philosophia Medici"—*Notes and Reflections*—grew to a prodigious size, and some of them at one time used to find their way into the *Guy's Hospital Gazette*, under the signature of "Pilocereus Senilis." It may be interesting to those old Guy's men who have retained copies of that students' journal to know from whose pen these remarkable essays proceeded. One of Moxon's most important papers was "The Explanation of the Association of Aphasia with Right Hemiplegia," published in the *Medico-Chirurgical Review*, wherein he put forward the view now generally adopted, that the left hemisphere takes the initiative in right-handed persons, whilst the right acts in unison with it, and so under ordinary conditions the left hemisphere controls the organ of speech. This theory has since been proved by the observation of aphasia in association with left hemiplegia in left-handed persons. Many of his papers are published in Guy's Hospital Reports, among which will be found "A Contribution to the History of Visceral Syphilis," "Syphilitic Disease of the Spinal Cord," "Atheroma of Arteries," "The Pathological Nature of Tumours," "Insular Sclerosis of the Brain and Spinal Cord," "The Albuminuria of Adolescents," &c. In 1881 he delivered the Croonian Lectures at the Royal College of Physicians on the "Anatominal Conditions of Cerebral and Spinal Circulation," wherein are described some original observations on the fourth ventricle, upon which, after laying in the dust the previously accepted views, he proceeded to construct some interesting theories of his own.

In 1878, Dr. Moxon, finding himself hemmed in by new buildings at Hornsey, purchased a house at Highgate, and, securing a large piece of ground in its vicinity, laid it out as a beautiful garden. In this he took the greatest interest, and amused himself in making frequent alterations and improvements. At one time he added a mountain-top covered with every Alpine plant; at another his fancy led him in the direction of little lakes and pools for the accommodation of aquatic plants and ferns. Every flower, wild or cultivated, found a home in his garden; and many had histories that brought back the thoughts of friends. Here, too, the wild birds from the Highgate woods flocked for food and certain protection. In the winter, lumps of suet and cocoa-nut sawn in rings were hung on the arches and boughs for the benefit of the tits, and loaves of bread were broken up for the blackbirds and thrushes, finches and sparrows. Always, before taking his own breakfast on a winter's morning, Moxon first saw to the feeding of his feathered friends. He was, indeed, an ardent lover of nature, to whom every flower in the hedgerows was familiar, and who in his studies had not even neglected to distinguish the various English grasses. Slight in figure and of a very delicate constitution, which showed signs of breaking even when he was a student, Moxon always worked to the extreme edge of his strength, but was buoyed up by a natural vivacity and an indomitable will. For years, when overworked, he was liable to attacks of hæmaturia, apparently dependent upon an excess of oxalates, and of late albumen had been noticed in the intervals of the attacks. Six years ago he on two occasions suffered from hæmoptysis, and was compelled to go abroad and rest for a term of three months. His delicacy of fibre also showed itself in attacks of ulceration of the cornea, whereby one eye became permanently defective in refraction. Of late he began to suffer, too, from periodic attacks of vomiting, occurring suddenly, for which he used to take hydrocyanic acid. Chloral also became frequently necessary to obtain sleep. But before the outside world he worked on as cheerfully as before, under an ever-increasing weight of practice. Still more recently another symptom appeared in the form of giddiness, with a feeling of numbness and weakness on the left side. He was suffering from one of these attacks in March last, but it passed off after a rest by the sea. To him they meant thickened arteries and impending paralysis or apoplexy. On the morning of July 21st he telegraphed to a friend to relieve him of his life-office work, but he nevertheless came to town in a state of suffering. At 1 o'clock he asked to be relieved of another appointment, and his friend, calling a little later, found him suffering from the symptoms before detailed. Afterwards he drove out to his mother's grave at Finchley, and, returning to finish his correspondence, appears, whilst suffering in the manner described, to have injudiciously taken a carelessly large dose of hydrocyanic acid, which in his low state of health doubtlessly precipitated the end.

Dr. Moxon was a devoted and loving husband, a kind and affectionate father, and a true friend. Generous, warm-hearted and benevolent, he was ever ready to lend a helping hand to those in distress. Many a poor student has been assisted through his difficulties, and many an orphan has been temporarily supported, by his open purse. The amount he thus gave away in private charity would be scarcely credited. Hospitable, and fond of entertaining, it was his delight to collect around his table men of thought and wisdom, and to introduce some abstruse problem for their discussion. Often, for the sake of argument, taking the weaker side, he would silence all speakers, and then, suddenly changing round, would show in what the fallacy of his former argument lay. Sensitive and tender-hearted, he was deeply affected by the sight of pain, and he rebelled against anything akin to oppression. How he stirred the College of Physicians and moved the whole profession in the Bower and Keates case is still fresh in the memories of all, and the triumphant result obtained was due mainly to his able advocacy. Of late, under the pressure of friends and editors, he had, at intervals, contributed to the *Contemporary Review*, and perhaps we cannot end this sketch of his life better than by quoting the final words of his last published essay: "True, the vital spark of heavenly flame does somehow hold one together. Yet faith is not for the body, nor is hope mere earthly expectation, nor is life all centripetal, nor is the future merely a coming present; and those who vulgarise our holy things do harm to all that is noble in humanity, whose faith must endure all things, with 'nevertheless not my will, but Thine,' trusting ever in One whose ways are not our ways, who sees good in everything we call evil, so as to permit it, and evil in everything we call good, so as to send it quietly away, and believing that the good God is always good to all, and strives to be good through all to all, and never fails, but only seems to men to fail."

We have been favoured by an esteemed correspondent with the following appreciative sketch of

WALTER MOXON AS A TEACHER.

Dead, did you say? Yes, dead! Dead?—that slim figure, that grey, searching, friendly-victimising eye, that low earnest voice that carried the beginner straight out of his depth, thinking only of the pleasure of the bath and nought of the risk of drowning? Dead?—that man of work-by-banter, of sparkling humour, writ, even to a stranger, by his slight oddities of manner and of gesture, brimfull of individualised nervous energy? Yes, dead! The sad surprise refuses to take root; it is impossible to believe it of Walter Moxon, whose natural talent these short long years has been at once our pleasure and our pride.

Short indeed seems the time since my first remembrance of him. Yet it carries one back nearly a quarter of a century, and over all those twenty years and more his intellectual gifts have freely sprayed their pleasurable refreshment. At first in the dissecting-room, when with his hat on and beflannelled, he was a somewhat weird-looking figure, that first-year's men fought shy of. Second-year's men had learnt to appreciate him and were fond of him. But to the very juniors in my day he was more identified with the Pupils' Physical Society, of which he was one of the honorary secretaries. Many of us, then spratlings, must remember him in various parts of the hospital making up to the fresh faces of the newly-opened session; and how, having fixed a man down, so to speak, with his eye, he would say, in somewhat measured, backward speech, "You come to the Physical Society of course, Mr. W——. All Guy's men come to the Physical." And then with a few words, putting one quite at ease with oneself and him, and with an irresistible "You will come to-night, won't you?" he had gone, having implanted a shaft, in the sensation of an indefinable charm, the force of which is best measured by what is most certainly the fact, that most of those he accosted went to the meetings in question, were cordially impelled towards a better knowledge of him, and that many of them subsequently often contributed to the discussions at the Society in obedience to the suasion of his look or his pen. We passed on together—he in his promotion to the offices of assistant-physician and Demonstrator of Morbid Anatomy, we in our pupilage. He used to do such ward work as attached to the former in the

mornings; and even in those days I well remember how his particular and original acuteness showed itself, for he never seemed to exhaust a case or to have said his last word about it. Were it some chronic case that had been in the wards for months, he had something new to say about it; some airy vision would be embodied for his clerks, to rehabilitate their jaded ardour and stir their interests in what, except under the illumination of his profundity of insight, imagination, and humour, would have remained but a dry bone indeed. I am afraid in those days, both in the out-patient room and in the wards, we sometimes thought him over-critical—"too clever by half," as we might have said,—and wanting in power to knuckle down to the pressing necessities of the student; but if so, it was due to a juvenile want of that depth in which he excelled and revelled. Moreover, after all, he was learning the rudiments himself; and in the wards and the out-patient room he studied harder than the best of us. But his special talent was at that time most displayed in the post-mortem room. The fringe of the class would still go in and out of the theatre (the audience in the dead-house is, I suppose, always a shifting one) and be little the wiser for the attendance. "What is the case?" "Goodness knows! There is Moxon talking away," are the question and answer I have often heard, and who of Guy's men of 1864 to 1874 does not remember him in very deed "talking away" with his fingers as much as by word of mouth. But there was always an inner ring of a goodly number of students who listened to him, talked with him, followed his play of thought and fancy as best they could, and who remember those demonstrations, so imbued were they with exhilarating and unwonted enjoyment, so original, so quick, so instinct with new light, with old light played in strange and varied combinations, as times which shaped their future study, and to which, whether as regards the matter or the manner in which the instruction was conveyed, they look back with the profoundest gratitude.

As a lecturer on Pathology and on Clinical Medicine I do not think he at first made much mark. Lectures on pathology were ill-attended in those days; attendance was not then compulsory; and in his lectures on Analytical Pathology he probably fired mostly over the heads of the few that came. And as regards his earlier clinical lectures, young students found difficulty in recognising the main road, he so often wandered in his journey down the shaded lanes, which even to the last seemed still to possess too much attraction to allow of lucidity, and which for those who were not familiar with his manner of thought made him difficult of comprehension. More experience made him less subtle; and, as showing how rapidly he gained a hold as a teacher, it may be said that on the occasion of his delivering the introductory lecture, not many years after his appointment on the hospital staff—an occasion, it need hardly be said, which has usually been considered by the audience as a fit opportunity for the indulgence of playful and irresponsible criticism of a somewhat harassing nature,—the crowded theatre from the commencement to its close was wrapped in absorbed attention. Moxon left the post-mortem room when he became full physician, and he next lectured on Materia Medica. Of these lectures it must suffice to say that they were of a piece with all his other work; they exhibited a most retentive memory, they were quite original, always amusing, and—a thing so difficult in this subject—the interest of his hearers was maintained to the last. In his ward work he had continued to increase in power and popularity as a teacher. While his vivacity of thought had remained irrepressible, his power of unravelling the problems of disease had become more conspicuous, and the two phases of his ability made an hour or two in the wards with him a time of which it would be difficult to say whether the pleasure or the profit were the greater. It is not my purpose to speak of his more public life. I shall only say that as he was in the wards of his hospital, and amongst us his pupils, so he was when speaking to his fellows at any of the Medical Societies. He was sure to draw. Whether in the ingenuity of his suggestion, the adroitness of his argument, the humour of his simile, the crispness of his epigram, or the general piquancy of his style, he was always clever, never commonplace.

Just the same, too, was he at his home. It is said that his colleague, Hilton Fagge, speaking of Moxon's tact and knowledge as displayed in his attendance upon him in his own last illness, described him as a perfect physician. I shall venture to say that he made a perfect host. He collected round him men of all ages and of all intellectual grades; and whether it was his youngest clinical clerk, or a first or second year's man, he drew him out and made him at home just as easily as he entered the lists with those of graver years, maturer knowledge, and more subtle reasoning powers.

There must be many who are now recalling the enjoyable quiet of a Saturday to Monday with Dr. and Mrs. Moxon at Hornsey or Highgate. Fond of his garden, he was ready for a stroll and a chat about roses or the plants in his greenhouse. If his guests were particularly energetic, he would walk with the lustiest of them and examine those who would submit in grasses or wild flowers. Back again at home, he would start upon Darwin, politics, metaphysics—anything, it mattered not to him. Nothing found him uninterested, for if he had little precise knowledge of the immediate subject, he was always well at home as a sort of intellectual *picador*—in and out amongst the disputants, now here now there, to keep up the vigour of the fight. He generally succeeded in the end in arraying everyone against himself, and then would come the fun—both his and ours—three or four at him, and he, by no means infrequently, with no case, as the barristers say. But such was his skill in dialectics, he was pretty sure to wriggle out of his difficulties and to score, at any rate, a seeming success. In this passion for disputation lay the secret of much of his success. He was always a kind man and ready to interest himself in the welfare of his clinical clerks or any of the students of the hospital with whom he came into more immediate contact: but it may be doubted whether he laid himself out with set purpose for their good, as that he delighted in the friction of men's minds—he revelled in it; and nothing, I think, gave him more real pleasure than to gather some friends round his table, or in his drawing-room with his wife, and to have a talk. On one such afternoon within memory someone proposed that Ruskin should be read; a volume of "Stones of Venice" was accordingly produced, and the reading commenced. The third line started Moxon, and we were off; and even the fascinations of that great and strange writer, with whose angularities of thought and eccentricities of expression I should suppose him to have had much responsive sympathy, were dead to us for that day. Moxon was, even at home, a master teacher, and if in a peculiar and inimitable way, none the less I think in the best sense. Teaching is direct or indirect: there is that which satiates, there is that which creates, appetite. Moxon's was essentially of the latter kind. He himself described it, not as food, but as mustard. It was highly seasoned, no doubt, and often, in consequence, produced indigestion, but always of that form which is attended by voracity. I think I may safely say there has been no man of my time at Guy's who has possessed so really marvellous a power of making men work. Gallingly caustic to the lazy, kind and painstaking with the slow, skilled in putting the diffident on better terms with themselves and their powers, quick for the clear-headed and acute, only unsympathetic—sometimes scornful—to the stupid and perverse, he seemed to sum up character with much keenness of insight, and to lead by a charm which was essentially his own.

His method occasionally did harm to the overweening or precocious, since it fostered and forced a self-respect which, in such, was already in too great abundance; and I believe it to be true, as I have heard said, that there were particular instances of deterioration under his training. This was, however, but seldom; probably in no case was the declension abiding, while an enthusiasm for observation and research was generated in overwhelming proportion. In this also was another element of his strength: he taught men to teach themselves, and by the attractiveness of the material he put before them he suggested how his hearers could make work attractive to themselves. No doubt, too, he repelled some. To such he was whimsical or unintelligible, but they had never got at him or taken the pains to understand him, and it was necessary for a student to be almost a disciple to fully enjoy him.

Dear Moxon—dear indeed to those who knew you intimately—there is a peculiarly fresh and springtime memory of those happy days now gone for ever. As I dwell on them, it is impossible to forget that the last time many of us heard you speak was when you proposed "The Past and Present Students of Guy's" at the recent biennial festival. You did not like that word *past*. For it you would substitute *perpetual*. Oh, tell us, had you a prevision that ere a month had gone you would belong to the one Perpetual, and that to our Past would be added such a poignant regret?

THOMAS WARD JESTON.

MR. THOMAS WARD JESTON, whose death, within a few days after entering upon his ninety-seventh year, occurred on the 18th inst. at his residence at Henley-on-Thames, was one of the few survivors of the Peninsular war. Born at Henley in 1790, he served his apprenticeship to the medical profession at Wallingford, and subsequently attended the Northampton, Guy's, and St. Thomas's Hospitals. In 1812 he was gazetted to the 36th Foot, and joined the British Army under Lord Wellington just after the battle of Salamanca. After sharing in the retreat from Burgos, he was sent to Vittoria, a day or two after the great battle, and was present at the battles of the Pyrenees, Nivelee, Nive, Orthes, and Toulouse, for the first four of which he received medals. At Toulouse, being struck down by dysentery and fever, he was invalided home, and being put on half pay at the end of the war, he established himself as a medical practitioner in his native town. In 1834 he was put on the Commission of the Peace, and was elected mayor, an honour four times afterwards bestowed upon him, the last occasion being so recent as 1881. Mr. Jeston was also the recipient of a medal awarded by the Society of Arts for improvements in the mode of obtaining opium from the poppy, and it was not till 1883 that he retired from active work. As a link with a great and glorious past, an interest attaches to him extending beyond the circle of his personal friends and his immediate neighbours, by whom his decease is sincerely regretted.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AT an ordinary meeting of the Council of the above College held on Thursday last (Aug. 5th) the minutes of the previous meeting were read and confirmed. Mr. Berkeley Hill was elected a member of the Council of Examiners in the place of Mr. John Croft, resigned.

The annual meeting of Fellows and Members is to be held on Thursday, November 4th, at 3 P.M.

A letter was read from the Master of the Society of Apothecaries inviting the College to admit the Society as a party to the Combined Examination instituted by the two Colleges. The letter was referred to the President, who was empowered to appoint delegates to confer with delegates from the Royal College of Physicians on the question.

The vacancy in the Examinership in Medicine created by the death of the late Dr. Moxon, and that in Midwifery by the retirement of Dr. Champneys, will be filled up in October. The next quarterly meeting of the Council of the College will also be held in October.

Medical News.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—The following gentlemen were admitted Members of the College on the 29th ult.:—

Collier, William, M.D. Camb., Oxford.
Gay, William, M.B. Edin., Disraeli-road.
Miner, Francis Leslie, M.D. McGill, Wimpole-street.
Pidcock, George Douglas, M.B. Camb., Downshire-hill.

The following gentlemen were admitted Licentiates of the College on the 29th ult.:—

Aikin, William Arthur, Clifton-place, Sussex-square.
Arnold, Ernest Charles, Argyle-street, Tynemouth.
Barber, Percival Ellison, Brookhill, Sheffield.
Barclay, Wilfred Martin, Cavynge-square, Clifton, Bristol.
Barnard, Walter Burrows, Upper Richmond-road, Putney.
Barrett, William Amherst Henry, Angell-road, Brixton.
Barsham, William Orridge, Lymington.
Bett, William Trinity-square.
Bhedwar, Pallonji Pestonji, Union-street, Burton-on-Trent.
Blacker, A. Barry, St. George's-road, Pimlico.
Blancard, Johnville Toly, Myddleton-square.
Blixland, Ernest Gregory, Sydney, New South Wales.
Blnett, George Mallack, Regent's-park-terrace.
Branson, Herbert William, Tavistock-road, Westbourne-park.
Burton, Leonard Wm., Terrace, Knatchbull-road, Camberwell.
Cave, Frank Evans, Glantlyv, Dorville-road, Lee.
Christmas, Charles Denn, Weltje-road, Hammersmith.
Clarke, Samuel Arathoon, Bolingbroke-road.
Collingwood, George Trevor, Manor-road, Brockley.
Comber, C. T. Thornton, Clarence-terrace, Priory-park, Kew.
Cox, James Herbert, Malmesbury-road, Bow.
Crocket, Wm. Caldwell, M.D. McGill, Tollit-street, Mile-end.
Crossley, Ely Wilkinson, Weymouth-street.
Damian, Francis George Claxton, Lupus-street.
Deane, Edward, Guy's Hospital.
Dickinson, William Lee, Chesterfield-street.
Du Boulay, Hubert Houssemayne, Lancaster-gate, Hyde-park.
Dunn, Philip Henry, St. Bartholomew's Hospital.
Dutch, Henry Asher, Sinclair-gardens, Uxbridge-road.
Engelbach, Frederick George, Fernleigh, Richmond, Surrey.
Fenton, Charles Francis, Western-road, Romford.
Forbes, Norman Hay, Bedford-park, Chiswick.
France, James Mead, Guildford-road, South Lambeth.
French, George Brooke, Royal Medical Society, Edinburgh.
Gault, Arthur Henry, Bramhall, Stoakport.
Girvin, John, Perry-hill.
Glasson, Charles James, Miles-road, Clifton, Bristol.
Glinn, Cornelius Frederick, Oxford-terrace, Edgware-road.
Goullett, Charles Arthur, Finchley-road, St. John's-wood.
Hackett, Harry Eugene, Lever-street, Manchester.
Harding, Charles O'Brien, Compton-terrace, Islington.
Harger, Frank Arnold, Castlenau, Barnes.
Harries, John Frail, King's College Hospital.
Hassard, Edward Moresby, Hoddesden.
Haynes, Edward J. Ambrose, Ashburnham-road, Greenwich.
Hontach, George Frederick, Hoxton House Asylum.
Hill, Walter James, Royal Hotel, Bath.
Hinde, Alfred Buckley, Middlesex Hospital.
Hutchesson, James, Nelson-street, Edinburgh.
Kapadia, Fardunji Sorabji, Camden-road, Holloway.
Labey, Julius, Harleyford-road, Vauxhall.
Lyle, Charles Convery Vacey, Maryland's-road, Paddington.
Montague, Arthur John Helm, St. Ann's Villas, Notting-hill.
Mudge, Zachary Belling, Claremont-square.
Nairn, Robert, Lambeth-palace-road.
Norman, Frederick Choumert-road, Peckham.
Pearse, Arthur William, Botesdale, Diss.
Penton, Richard Hugh, Sewardstone-road, Victoria-park.
Pocock, Herbert Jones, Worcester-terrace, Clifton, Bristol.
Rickards, Henry William, Russell-square.
Robinson, Bernard, Edith-road, West Kensington.
Roper, Harold Kenmaway, St. Olave, Waldengrave-road, Upper Norwood.
Roughton, John Paul, St. Julian's-road, Streatham.
Rowell, George, Guy's Hospital.
Scatliff, Philip Melancthon, Macaulay-road, Clapham-common
Smallpeice, William Donald, Queen Anne's-gate.
Snow, Lionel Mason, King Henry's-road, Primrose-hill.
Stabb, Ewen Carthew, Ilfracombe.
Tonking, John Herbert, Carn Brae.
Treglimnick, Albert Stephen, Claremont square.
Tubby, Alfred Herbert, Kennington-park-road.
Walcham, Charles Henry, Amhurst-road, Hackney.
Ward, Stanley Edward, Haverhill.
Webb, William Henry, Brook House, Upper Clapton.
Wilson, Arthur Edward, Wickham-road, Brockley.
Wookes, Arnold Beaumont, Harley-street.
Wright, George Cornelius William, Rawcliffe, Selby.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted Members of the College at a meeting of the Court of Examiners on July 28th:

Barsham, W. Orridge, L.R.C.P. Lond., Fincham, Norfolk.
Bradbury, John Augustus, L.S.A., Denmark-hill.
Brushfield, Thomas, Burleigh.
Collins, Frank, Adelaide-road.
Cook, Robert James, East Dulwich.
Denman, Robert, L.S.A., Sydenham.
Engelbach, Frederick George, L.S.A., Richmond.
Forbes, Norman Hay, L.R.C.P. Lond., Chiswick.
Griffin, John Hubert, L.S.A., Hammersmith.
Manby, Edward Petronell, Trinity-square.
Nason, Edward Noel, Nuneaton.
Pockett, Lewis Walter, L.S.A., Gool.
Rains, Robert Harding, Levenshulme.
Stabb, Ewen Carthew, L.S.A., Ilfracombe.
Stevens, William Henry, Bristol.
Tonking, John Herbert, L.R.C.P.Lond., Pool, Cornwall.
Wheaton, Samuel Walton, L.R.C.P. Lond., Battersea-park.

Admitted on the 29th ult.:—

Briant, Arthur John, L.S.A., Liverpool.
Brown, William Henry, L.S.A., Oxburgh.
Clarke, Samuel Arathoon, L.R.C.P. Lond., West Kensington.
Dickinson, William Lee, L.R.C.P. Lond., Chesterfield-street.
Fowler, John Bucknell, L.S.A., Harrington-street.
Furnivall, Bryan, L.R.C.P. Lond., Bishopsgate-street Without.
Holland, Edmund Burke, Titchfield-terrace.
Jones, Sydney Harold, L.S.A., George-street, Hanover-square.
Malden, Walter, M.B. Cantab., Ventnor.
Mugford, Sidney Arthur, Dean-street.
Shelswell, William Arthur, Banbury.
Shopoff, Pano Ivan, L.R.C.P. Lond., Upper Brook-street.
Wilson, Arthur Edward, L.R.C.P. Lond., Brockley.
Woodhouse, Francis Decimus, Dorchester.

Admitted on the 30th ult.:—

Burton, Charles Frederick, L.S.A., Harrogate.
Charlesworth, George Henry, L.S.A., Wandsworth.
Cunliffe, William Shrubsole, L.S.A., Stoneleigh.
Goodman, Thomas Herbert, L.S.A., Strand.
Luff, Arthur Pearson L.S.A., Ealing.
Rowell, George, L.R.C.P. Lond., Trinity-square.
Skelding, Henry, Euston-square.
Stockton, Hubert Samuel, L.S.A., Wray-crescent.

Admitted on the 2nd inst.:—

Biddlecombe, Edward Henry, L.R.C.P. Lond., North Allington.
Evans, John Morgan, L.R.C.P. Lond., Penyboat, Radnor.
Sankey, Julius Ivor, Notting-hill.
Thompson, Ernest Atherden, Wandsworth-common.

Admitted on the 3rd inst.:—

Fenoulhet, James Peter, Lee, Kent.
Phillips, William Edward Picton, L.S.A., Haverfordwest.
Wright, G. Cornelius Wm., L.R.C.P. Lond., Rawcliffe, Selby.

UNIVERSITY OF ABERDEEN.—The lectures at Marischal College closed on July 16th, and the Professional Examinations began the day following. A large number of candidates appeared for examination, and, as usual, about 50 per cent. were rejected. The closing ceremony, the "capping," took place on Saturday, the 31st ult., when 17 were promoted to the degree of M.D. and 62 received the degrees of M.B. and C.M. The following is the list of successful candidates:—

DEGREE OF M.D.

Anderson, John Hector.
Argo, George Collie.
Booth, James Mackenzie.
Ferguson, William Balfour.
Geddie, William.
Holmes, William Reid.
Inglis, John.
Macdonald, Peter William.
Mathieson, John.
Morrison, Arthur Andrew.
Mutch, Forbes Robertson.
Reid, John.
Robb, James Taylor.
Smith, Alexander Gillespie.
Stericker, William.
Sullivan, Peter Alfred.
Taylor, John.

DEGREES OF M.B. AND C.M.

Aird, Charles Mitchell.
Angus, Henry.
Arnold, Charles Arthur.
Barnes, Joseph Marshall.
Barrett, Charles Wm. Sessions.
Bennett, Thomas Charles
Binnie, John Fairbairn.
Brown, Henry Havelock.
Burgess, Greg r.
Chapman, Arthur Wilson.
Clark, Alex. Forbes Chisholm.
Collie, Frank Lang.
Coward, Ernest George.
Dalgarno, Alexander William.
Davidson, William.
Dickie, James Steel.
*Duffus, John Charles Grant.
†Findlay, George.
Forbes, Charles Frederick.
Forbes, George.
Forbes, Henry Farquharson.
†Galloway, James.
Geddie, William Stewart.
Gray, William Henry.
Greig, William.
Grieve, Alexander Nathanael.
Hewlett, William Henry.
Hutchinson, Arthur Cayley.
Ingram, Alexander Gordon R.
Jameson, Alexander Seymour.
Lewis, James Thomson.
Lumsden, Philip James.
Macdonald, Donald G. Gordon.
Mackay, Alfred.
Macrae, Farquhar.
Malcolm, John.
Martin, Edmund Thomas.
†Milligan, William.
Milne, Alexander.
Milne, G. Leslie Hodgson.
†Murray, James.
Nicol, James.
Orchard, Edward Russell.
Reid, Charles.
Reid, George Marr.
Reynolds, Graham Hay.
Robertson, Cecil.
Ross, Hugh.
Russell, John.
Scatterty, William.
Shirres, David Alexander.
Simpson, Alexander.
Smith, John Wesley.
Stenhouse, John Hutton.
Souza, Edwardo Marciel de.
Stephenson, Robert Ben Tydd.
Taylor, John.
Thomson, James.
*Thomson, John Duncan.
Twining, Vincent Wing.
Urquhart, William Donald.
Williamson, George.
Wills, Reginald Graham.

* Highest Academical Honours. † Honourable Distinction.

UNIVERSITY OF GLASGOW.—The following degrees were conferred in the Faculty of Medicine on July 29th:—

DEGREE OF M.D.

Aitken, John, M.B., C.M.
Alexander, Samuel, M.B., C.M.
Auld, Alex. Gunn, M.B., C.M.
Buchanan, John, M.B., C.M.
Carruthers, John, M.B., C.M.
Duff, John, M.B., C.M.
Dunlop, T. Cameron, M.B., C.M.
Lawson, J. Burnett, M.B., C.M.
†Rankin, Alexander, M.B., C.M.
Sinclair, Eric, M.B., C.M.
Skottowe, Alex. J. F., M.B., C.M.
*Somerville, William Francis, M.A., B.Sc., M.B., C.M.
*Stewart, Robert Sloss, M.B., C.M.
Waddell, William, M.B., C.M.

DEGREES OF M.B. AND C.M.

‡Aird, Alexander Wallace.
Adam, Basil John.
Banks, Charles.
Baxter, Colin.
Beattie, Robert M'Glie.
Broom, John.
Brown, James Andrew.
Brown, Robert, M.A.
Brown, Walter Falconer.
Bruce, James.
‡Bryce, Alexander.¶
Campbell, Archibald, M.A.
Campbell, Archibald Thomson.
Carmichael, Alexander.
‡Carslaw, John Howie, M.A.
§Connal, James Galbraith.
Corbett, Robert.
Craik, Robert.
Crawford, Alexander David.
Cullen, John Robert Fleming.
Currie, John.
§Dewar, Daniel M'Kellar.
Dodd, John.
Downes, Joseph Lockhart.
§Dunlop, James.
‡Fergus, William Henry.
Ferguson, George Gumis.
Ferguson, Robert Thomson.
Gardner, Robert Irvine.
Goff, Bruce Edward.
Gray, Andrew.
Gray, Charles.
Haddow, Robert Wilson Taylor.
Hamilton, Robert.
Hannah, William Tweed.
Hay, Walter.
Henry, Robert.
Highet, Robert Campbell.
Hill, James Wright.
Hughes, Arthur Davies.
Jago, Josiah.
Keddie, John.
Kennedy, John Alexander, M.A.
Lourie, James.
§Macphail, John.
MacColl, Donald Stewart.
Macdonald, David.
Macdonald, Thomas Ross.
Maclachlan, Archibald.
Maclachlan, James.
MacLean, Alexander Henderson.
MacLeod, David Thomas.
M'Conechy, James.
M'Donald, James.
M'Houl, Hugh Miller.
M'Intyre, George.
M'Kinlay, William.
‡Mair, Robert.
§Manners, William Henry.
Miller, Robert Craig.
Monteagle, Henry Ward Beecher.
Muirhead, James.
Nicholson, William Thomas.
Nicoll, James Henderson.
§Nisbet, Adam T.
Penman, Robert Steven.
Phillips, William Fleming.
Pyle, William.
Rae, James.
Robertson, Robert.
Robertson, William.
Robinson, Harry Watt.
Routledge, Robert.
Roxburgh, Alexander.
Roxburgh, Archibald.
Scanlan, Charles Edward.
Shand, William.
Sinclair, Henry Williamson.
‡Snodgrass, William, M.A.
Steil, Jas. William Handcock.
Stewart, John.
Stewart, John Barclay, M.A.
‡Stewart, John.
Thorburn, John.
Watt, Thomas, M.A.
Whitelaw, Robert.
Wingate, Donald.
Wylie, Alexander.
Wylie, James.
Young, John.

DEGREE OF C.M.

Chalmers, John, M.D.

Received the degrees of M.B. and C.M. on July 26th:—

Fox, Walter.

* Highly commended for Thesis. † Commended for Thesis.
‡ Honours. § High commendation. ¶ Commendation.
¶ Mr. Bryce gains the Brunton Memorial Prize of £10, awarded to the most distinguished Medical Graduate of the year.

BRITISH MEDICAL SERVICE.—The following Surgeons on probation in the Medical Department of the British Army were successful at both the London and Netley examinations held on July 30th. The prizes are awarded for marks gained in the special subjects taught at the Army Medical School. The final positions of these gentlemen are determined by the marks gained in London added to those gained at Netley, and the combined numbers are accordingly shown in the list which follows:—

	Combined Marks.		Combined Marks
*Davidson, J. S.	5575	Donegan, J. F.	4200
†Will, J.	5565	Donaldson, J.	4195
Moir, J.	5383	Mathias, H. B.	4175
Fallon, J.	5375	Bent, G.	4168
Salvage, J. V.	5308	Barefoot, G. H.	4166
Fowler, J. F. S.	5210	Newland, F. R.	4160
Aldridge, A. R.	5190	Windle, R. J.	4143
Bostock, E. A.	5008	Hall, R. J. D.	4120
Fayrer, J.	4992	Marder, E. S.	4115
Walker, C. F.	4950	Allport, C. W.	4042
Macdonald, C. J.	4930	Russell, J. J.	4030
Tatham, C. J. W.	4907	Edye, J. S.	4013
Clarkson, T. H. T.	4898	Scott, G.	4005
Austin, H. W.	4715	Browning, T.	3982
Garner, C.	4689	Bate, L. A. F.	3960
Wright, R. W.	4685	Trotter, W. J.	3910
Bailey, W. F.	4665	Hosie, A.	3905
Eckersley, E.	4655	Marks, G. F. H.	3896

* Gained the Herbert Prize of £20, with the Montefiore Medal and Prize of 20 guineas.
† Gained the Martin Memorial Gold Medal.
‡ Gained the Montefiore Second Prize and also the Prize presented by Surgeon-General W. C. Maclean, C.B.
§ Gained a Prize in Pathology, presented by Sir Joseph Fayrer.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—At a meeting of the Court of Examiners, held on July 19th and following days, the undermentioned were admitted Licentiates of the College:—

Thos. G. Barton, Louis Buggy, Edward Corcoran, Thos. A. Connellan, Robert H. Cox, William B. Dick, St. Leger John Edmundson, Victor Fenton, William Greene, Richard M'Hugo, Edmund J. Jacob, John F. Kennedy, John Langan, Sinclair A. Long, Victor E. Ludlow, Philip McDermott, Henry J. Mathews, Jeremiah Nally, John W. O'Brien, Joseph O'Meara, Francis G. O'Donohoe, Joseph O'Connor, Denis Joseph O'Loughlin, Francis J. Reid, Thos. J. Rossiter, William L. Ross, Thomas Williams, Thos. H. Wilson, Charles S. Woodwright, William H. Woodwright, Edward Yates.

SOCIETY OF APOTHECARIES.—The following gentlemen have been appointed a Court of Examiners of this Society for the ensuing year:—Henry Bullock, L.S.A., F.R.C.S.E.; Andrew Clark, L.S.A., F.R.C.S.E.; William A. Duncan, L.S.A., M.R.C.P. Lond., F.R.C.S. Eng., M.D. Brussels; Robert Fowler, L.S.A., M.D. Univ. Edin., M.R.C.P. Edin., M.R.C.S.; F. de Havilland Hall, L.S.A., M.D. Univ. Lond., F.R.C.P.L., M.R.C.S.; Frederick J. Hensley, L.S.A., M.D. Lond., M.R.C.S.; Robert J. Lee, M.D. Univ. Camb., F.R.C.P.L.; G. H. Makins, L.S.A., F.R.C.S.; John Sherwood Mocker, L.S.A., M.R.C.S., M.D. Univ. Lond., M.R.C.P.L.; John Charles Thorowgood, L.S.A., M.R.C.S., M.D. Univ. Lond., F.R.C.P.L.; W. J. Walsham, L.S.A., F.R.C.S. Eng., M.B., M.S. Aberd.; Francis Warner, L.S.A., M.R.C.S.E., M.D. Univ. Lond., F.R.C.P.L.

The following gentlemen passed their examination in the Science and Practice of Medicine, Surgery, and Midwifery, and received certificates to practise, on the 29th ult.:—

Bower, William George, The Vineries, Southport.
Briant, Arthur John, Bootle Borough Hospital, Liverpool.
Barton, Chas. Fredk., M.R.C.S., South Para Villas, Harrogate.
Cantliffe, Wm. Shrubsole, M.R.C.S., Torrington-square.
Goodman, Thomas Hubert, Strand.
Henderson, George Christopher, M.R.C.S., Natal, S. Africa.
Hunt, Howard Wraugham, M.R.C.S., Holford-square.
Paige, Horace Bennett Wood, Whitley, Newcastle-on-Tyne.
Plant, Alex. Whitmore, Wordesley, Stourbridge.
Popham, R. Brooks, L.R.C.P., L.R.C.S., L.F.P.S.G., Bartholomew-road, Camden-road.
South, Fredk. William Berry, San Nicolas, St. Leonards-on-Sea.
Stockton, Hubert Samuel, Wray-crescent, Tollington-park.
Watson, Henry Gervase, Moorfields, Sheffield.

OBSTETRICAL SOCIETY OF LONDON.—The Library of the Society will be closed from Aug. 16th to Sept. 16th.

GUY'S HOSPITAL.—The Library of this hospital will be closed to-day (Saturday) at 3 P.M., and reopened on Monday, Aug. 30th, at 9.30 A.M.

A DEMONSTRATION of the friendly and trade societies of Darlington in aid of the funds of the local hospital took place on the 1st inst.

ROYAL UNIVERSITY OF IRELAND.—By the sudden death of Mr. Curtis who was elected a senator of this university last week, a vacancy has taken place for a member of the Senate.

VICTORIA UNIVERSITY.—At the recent examinations at this University six candidates (two in the first division) passed Part 1 of the Final Examination for the degree of M.B.; five passed Part 2 of the same examination; seven the Intermediate Examination; and twenty-two the Preliminary Examination in Science.

HOSPITAL FOR THE ISLE OF MAN.—On July 26th, the foundation stone of a new hospital and dispensary was laid in Douglas by Mrs. H. B. Noble, who with Mr. Noble has given the site and £5000 for the erection of the building. Accommodation will be provided for 14 male and 14 female patients in the general wards, and there will be beds also for 28 patients in smaller wards. Several private wards will likewise be provided.

SANITARY CONDITION OF DUNGARVAN.—Dr. O'Farrell, Inspector of the Local Government Board for Ireland, reports in the following terms as to the sanitary condition of this place:—"The town is not well kept. Animals are domiciled in some of the cottages. The scavenging is inefficiently performed, the pavement and water-tables of the lanes being disgustingly dirty. There is no supply of potable water. It is sold through the streets, as in Spanish towns, at a halfpenny the four gallons. The sewers have but a slight gradient, and there is no means of flushing them." The Town Commissioners, to whom this report was referred, have taken no action.

BRITISH DENTAL ASSOCIATION.—The annual general meeting of the members of this Association will be held in the theatre of the Royal School of Mines, Jermyn-street, and in the Dental Hospital of London, Leicester-square, on the 19th, 20th, and 21st of the present month. An address will be delivered by Sir Edwin Saunders, F.R.C.S., the President elect, and papers on various subjects have been promised by Mr. Morton Smale, Mr. T. Charters White, Mr. S. J. Hutchinson, and others. The annual dinner of the Association will be held on the 20th inst.

MEDICAL STUDENTS AND COMPULSORY MILITARY SERVICE IN AUSTRIA.—Austrian medical students who, like other university men, are only obliged to serve in the army for one year, during which period they are miscalled "volunteers," have hitherto been allowed to serve their time while pursuing their medical studies. A new arrangement has, however, just been made by which six months only of the "volunteering" may be served during the period of medical study, the remaining half-year being deferred until after the M.D. degree has been obtained, and being occupied in medical and sanitary duties. These regulations will not come into force until after the completion of the next academical year.

PRESENTATION TO DR. FERGUS.—On the 24th ult. the old students at, and friends of, Marlborough College made a presentation to Dr. Walter Fergus, who, it will be remembered, recently relinquished his appointment as medical officer of the College after thirty-seven years of assiduous and highly successful work. The testimonial consisted of a portrait of the recipient, which it has been decided shall occupy a space in the large hall of the institution, a purse containing 400 guineas, and an illuminated address, recording the gift and signed by the long list of subscribers—579 in number. The presentation was made by the master, the Rev. G. C. Bell, who described the origin of the fund, and feelingly alluded to Dr. Fergus's long connexion with, and many services to, the College. The Bursar, the Rev. J. S. Thomas, and Mr. H. Richardson having spoken in similar strains, Dr. Fergus responded in suitable terms, and the proceedings terminated.

ST. ANDREWS GRADUATES' ASSOCIATION.—At a special meeting of the Council of the Association held at 11 Chandos-street, London, on Thursday July 29th, the following resolutions were proposed and carried:—1. "That this Council, at a special meeting to consider the question of direct medical representation in the Council of Medical Education, decides to support the candidature of Dr. B. W. Richardson, F.R.S., and to ask and invite the members of our Association and all St. Andrews graduates, the graduates of other Universities, and the profession generally, to support its candidate, believing Dr. Richardson to have identified himself with the interests of the general practitioners, and that he will fully support their interests and the interests of the profession." 2. "That a committee be formed to secure the election of Dr. Richardson as direct medical representative in the General Medical Council." 3. "That the following gentlemen form the committee, with power to add to their number—viz.: Sir J. Crichton Browne, M.D. (Chairman); Surgeon-General Gordon, C.B., M.D. (Vice-Chairman); F. H. Alderson, M.D. (Hon. Treasurer); R. J. Banning, M.D. (Hon. Secretary); Surgeon-Major Duka; Drs. Bright, Maurice Davis, Henty, Longhurst, Pickett, Royston, Savory, and Wyman.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

BARRETT, GILBERT LACY, L.R.C.P.Lond., M.R.C.S., has been appointed Medical Officer of Health for the Spalding Urban Sanitary District, vice Morris, resigned.

BOWKETT, THOMAS E., M.R.C.S., L.S.A., has been appointed Medical Officer to the Workhouse of the Poplar Union.

DAVIES, T. L. KENRICK, M.B.Edin., has been appointed Medical Officer for No. 2 District of the Conway Union.

DRUMMOND, ALEXANDER P., M.B., C.M.Ed., has been appointed Medical Officer for the First Dolton and Second Dolton Districts of the Torrington Union.

FOWKE, F. W., M.R.C.P.Ed., M.R.C.S., has been appointed Medical Officer for the Priors Marston District of the Southam Union.

GARMAN, J. CORNELIUS, L.R.C.S., L.R.C.P.Ed., has been appointed Medical Officer for the Brewood District of the Cannock Union.

GRANT, J. DUNDAS, M.A., M.D., F.R.C.S.Ed., late Assistant-Surgeon to the Central London Throat and Ear Hospital, has been appointed Full Surgeon to that Institution.

HALL, EDWARD, M.R.C.S., L.S.A., has been appointed Medical Officer for the Llanllwchaiarn District of the Newtown and Llanidloes Union.

HIND, ALBERT, L.R.C.S.Ed., L.S.A., has been reappointed Medical Officer of Health for the South Molton Urban Sanitary District.

HODGSON, MICHAEL, B.A.Dur., M.B., C.M.Ed., has been appointed Medical Officer for the Chipping Warden District of the Banbury Union.

JACKSON, MARK, M.D., M.R.C.S., has been appointed Medical Officer for the Second District of the Barnstaple Union.

LARKING, ARTHUR ERNEST, M.B.Dur., M.R.C.S., L.S.A., has been appointed House-Surgeon to the Parent Institution of the Brighton, Hove, and Preston Dispensary, vice Gerald Hodgson, M.R.C.S., L.S.A., resigned.

LIPSCOMB, H. R. S., L.R.C.P.Lond., M.R.C.S., has been appointed Medical Officer for the Kenton District of the St. Thomas Union.

NEVINS, ARTHUR E., M.R.C.S., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed House-Surgeon to the Middlesex Hospital, vice Clement Pound, L.S.A., whose term of office has expired.

PRAGER, ALFRED, L.D.S., has been appointed Honorary Consulting-Dentist to the Pimlico-road Free Dispensary, vice Lovejoy, deceased.

SULLIVAN, E. J. H., M.D., M.Ch., Q.U.I., has been appointed Medical Officer for the Fourth District of the Hemsworth Union.

Births, Marriages, and Deaths.

BIRTHS.

BOSWELL.—On the 27th ult., at Ashburne, Derbyshire, the wife of Alexander Boswell, M.D., of a son.

DEAN.—On the 1st inst., at Northleach, Gloucestershire, the wife of Francis Dean, M.R.C.S., of a daughter.

GREENWOOD.—On the 29th ult., at 3, Crouch-end-crescent, Hornsey-rise, N., the wife of A. Greenwood, L.R.C.P.Lond., of a son.

HUNTER.—On the 3rd inst., at Norfolk-crescent, Hyde-park, the wife of Sir W. Guyer Hunter, K.C.M.G., M.P., of a daughter.

KING.—On the 3rd inst., at Sutton Court-road, Chiswick, the wife of Wm. Moore King, M.R.C.S., of a daughter.

MARRIAGES.

ALFORD—KING.—On the 31st ult., at St. James's Church, Spanish-place, Henry J. Alford, M.D., of Taunton, to Marian, daughter of the late John King, of St. John's-wood.

BARLOW—SMITH.—On the 29th ult., at the Baptist Church, Astwood-bank, Robert Barlow, M.R.C.S., to Mary Ann, youngest daughter of James Smith, J.P., of Doe-bank House, Astwood-bank, Worcestershire.

CREASY—MARKBY.—On the 28th ult., at Holy Trinity Church, Paddington, Rolf Creasy, M.R.C.S., L.R.C.P., of Winslow, Bucks, to Mary, second daughter of Henry Markby, of Westbourne-terrace, Hyde-park.

HINE—BROWN.—On the 1st inst., at St. Andrew's Church, Bristol, Samuel D. Hine, M.R.C.S., L.S.A., of Ilminster, to Emily, daughter of Capt. George Brown, of Montpelier, Bristol.

ROBINSON—WILSON.—On the 29th ult., at Trinity Church, Claughton, Cheshire, Frederick William Robinson, M.B., C.M., of Huddersfield, to Janet Brocket Ritchie, daughter of J. Moncrieff Wilson, of Devonshire-place, Claughton.

RUSHBROOKE—PENHALL.—On the 31st ult., at City-road Wesleyan Chapel, Thomas Rushbrooke, M.A., M.R.C.S., L.R.C.P., to Louisa, daughter of Mr. George Penhall.

DEATHS.

BUSBY.—On the 27th ult., at the Paragon, Bath (after a long and painful illness), Alexander Ralph Busby, M.R.C.S., in his 44th year.

GITTINS.—On the 23rd ult. (after a short and painful illness), John Gittins, M.R.C.S., L.R.C.P., L.S.A., of St. John's, Horselydown, S.E., in his 45th year.

GORDON.—On the 3rd inst., at Woodlands, West Hoathly, Archibald Gordon, M.D., C.B., L.H., Inspector-General of Hospitals, and Hon. Surgeon to H.M., of Cornwall-gardens, Queen's-gate, in the 75th year of his age.

GRANT.—On the 23rd ult., at Cairo, Egypt, Ada Torrey, wife of Dr. Grant, Bey, M.D.

HOYLE.—On the 28th ult., at the Square, Tyldesley, Manchester, William Hoyle, M.R.C.S., L.S.A., aged 49.

KITCHING.—On the 1st inst., at Heworth, York, Walter Kitching, M.R.C.S., L.R.C.P., late of Clapham, Surrey.

LEIGH.—On the 26th ult., at The Grove, Arnold, Notts, George William Leigh, M.R.C.S., aged 75.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

METEOROLOGICAL READINGS.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

We cannot undertake to return MSS. not used.

LIQUOR STATISTICS.

LAST year the British spirits retained for home consumption amounted to 26,609,488 gallons, 0·733 of a gallon per head of a population estimated at 36,325,115. The foreign and colonial spirits consumed represented 0·221 of a gallon per head, the quantity being 8,012,655 gallons. The amount of foreign wines consumed was 13,767,928 gallons, 0·379 of a gallon per head; of beer, 27,101,238, or 0·746 of a barrel per head; of tea, 182,408,839 lb., equivalent to 5·022 lb. per head; of coffee, 32,660,320 lb., 0·898 of a pound per head. These figures show a large falling off in the consumption of British spirits, nearly 2,000,000 gallons; a falling off of some 300,000 gallons of foreign spirits; and a slight decline in the consumption of foreign wines. Beer showed a slight increase in the total consumed, but not on the amount per head of the population. Nearly 20,000,000 lb. more of tea were consumed, and coffee also showed a slight improvement. These statistics must be highly encouraging to advocates of temperance, being an undoubted proof that their labours in the past have not been without effect.

A. L.—The institution named has not been subjected to inspection by our commissioners.

Dr. F. W. Kirkham.—The right to do so is indisputable.

LUNATIC ASYLUMS IN SWITZERLAND.

To the Editor of THE LANCET.

SIR,—I beg leave to state, for the information of your correspondent, "F. G.," in reply to his communication in your issue of this day regarding the localities of asylums for the insane in Switzerland, that twelve Swiss cantons possess public asylums, and seven private asylums. Of the public asylums the cantons of Zurich and Thurgovie have two each, whilst Berne, Lucerne, Fribourg, Soleure, Bâle-Ville, St. Gall, Argovie, Vaud, Neufchâtel, and Geneva each have one only. The largest of these public institutions are the two in Zurich; they are together capable of containing 820 patients. The ten cantons which possess no lunatic asylums arrange to send patients to asylums in the cantons already named as possessing them. The oldest asylum in Switzerland is that at Geneva; it was founded in 1838. The most recent is that at Marsens in Fribourg, established in 1875. Besides these public asylums, there are also private asylums (some of them on a large scale, such as those at Stammheim and Männedorf in Zurich) situated in Geneva, Berne, St. Gall, Argovie, Thurgovie, and Vaud.

I am, Sir, your obedient servant,

West Malling Asylum, Kent, July 31st, 1886. JAMES ADAM, M.D.

A VACCINATION CENSUS.

MR. WILLIAM TEBB, who seems to devote his life to the disparagement of the most life-saving discovery of medical science—viz., vaccination, has given in *The Times* the results of a census meant to test popular opinion on the question. We have little respect for such statistics, which can be collected by any dissatisfied person. Everything untoward that happens about the post-vaccination age is readily attributed to vaccination, without respect to accuracy, and in entire ignorance of the frightful sequelæ of small-pox, which are the alternative to the slight inconvenience which sometimes follows vaccination.

THE ire of *One of the Public* is surely a little misplaced. The sentence quoted by our correspondent appears to be quite in the direction of his own sentiments.

A. S. might consult the Charities Register, published by Longmans.

DRAINAGE AND DISPOSAL OF SEWAGE.

To the Editor of THE LANCET.

SIR,—If the contributor of the annotation in your last issue (p. 217) on the disposal of sewage at Yarmouth had studied and experimented on the subject as he ought before unconditionally approving the abominable habit of corporations and engineers of discharging sewage into the sea, he would have known it is not a matter of the slightest importance, when a right system of drainage is adopted, whether what is called the outfall is under or above low-water mark. I say it is outside the question because no engineer who knows his work, and has any inventive faculty about him, would ever resort to the disgraceful and ignorant expedient of making God's beautiful sea a national cesspool. Yet the doing it seems to be the acme of wisdom that an engineer can obtain. Not only is the folly of polluting the sea being perpetrated at Yarmouth, but at the neighbouring town of Lowestoft and other towns as well. The engineers and authorities of these and other towns will, perhaps, endeavour to excuse themselves by saying: "We are surely not responsible, for we only copy the blunders of other men, and follow the example of now notorious London." To some extent, perhaps, the sarcasm is rightly applied, because, as London appears to be the guide in matters of social good, she ought to be ashamed of having the imputation so justly hurled at her of being the worst and most pestilential river poisoner in the world.

What are the facts? The Metropolitan Board of Works have courteously sent me the report of their committee, who are at their wits' end on the subject of London sewage. No wonder, for the condemnatory fact stares them in the face that they are daily discharging 180,000,000 gallons of sewage into the Thames at the two outfalls of Barking and Crossness, and how to diminish or extinguish the quantity they have not even the semblance of a good idea. Worse still, they do not seem willing to learn. The solid, fæcal and otherwise, to be obtained from 150,000,000 gallons of sewage represents, by the accepted rule, 1434 tons, 18 cwt. a day. To tell those who have practically experimented with the article that it does not represent an adequate manurial money value, if unspoiled by chemical reagents to decompose and unfit it for use, is simply a denial of visible facts to the contrary. Properly manipulated it would be eagerly bought for agriculture and gardening at £2 a ton, guano being £12. Yet the Metropolitan Board of Works ignorantly throw away such a source of wealth to themselves and the ratepayers, despite the suggestion of value given them by Colonel Jones and Mr. Bayley Denton. These gentlemen, the Board of Works state in their report, applied to the Home Secretary for all the sewage of London, and asked that the Board of Works should pay them in addition the modest sum of £110,000 a year! The Metropolitan Board, of course, were unable to comply. They will therefore continue to pollute the sea. In time, no doubt, some financial philanthropist will arise to seize this source of wasted wealth for his own and the public good.

I am, Sir, your obedient servant,

Batoum Gardens, W., Aug. 1st, 1886. W. HEMPSON DENHAM.

Progress.—Some of the wants indicated in our correspondent's letter are already met; others, for the most part, must be left to be supplied by the good sense and consideration of the public. We do not see that any useful purpose would be served by inserting the communication.

Mr. Robson (Leeds).—In an early number.

LONDON CONVALESCENT HOME.

To the Editor of THE LANCET.

SIR,—With regard to the scheme for a London Convalescent Home, can you inform me if it is in contemplation to erect such a home in or near town; and if so, is it likely that a seaside branch will be associated with it? I ask this because, as medical men, we all know the marvellous effect of change, combined with pure sea breezes, and how magically they act in perfecting cures. There is a building now vacant at Walton-on-the-Naze, of considerable capacity, facing a wide expanse of the German Ocean, which was formerly a large marine hotel. It contains numerous rooms, is in many ways suitable for a convalescent hospital, and may be had cheap. The death-rate at Walton is marvellously low, the distance from London inconsiderable, and the place is a very paradise of health for young children; so that I hope its advantages may not be lost sight of.—I am, Sir, yours faithfully,

HENRY GRAMSHAW, L.R.C.P., &c.

Walton-on-the-Naze, July 31st, 1886.

THE HYGIENE OF THEATRES.

DR. P. RENK, Professor of Hygiene at Munich, has recently endeavoured to solve the following problem:—Given a spacious theatre crowded during an evening performance for a certain number of hours, what is the difference of the effects on its atmosphere produced by the electric light or by gas, particularly as to the temperature and the generation of carbonic acid? Taking the Theatre Royal of Munich, which is lighted by 1400 lamps on the Edison system, he tested the two kinds of illuminants, with the following results:—During a representation which lasted from 5.30 to 10.15 P.M., and was witnessed by 1790 people, he found that while the rise in temperature in the pit was 11·1°C. with gas, it was only 7·7°C. with the electric light, and that in the upper gallery it was 10·7° with the former, and not more than 7·4° with the latter. As to the increase in the production of carbonic acid the results were equally important. In the pit it was as 2176 with gas to 1221 with the electric light, and in the upper gallery as 2655 with the first to 1430 only with the second.

Dr. Harries.—We cannot afford space for the continuation of the controversy.

Deutschland.—We see no reason why our correspondent should not do so.

HOSPITAL SUNDAY FUND AND THE WORKING CLASSES.

To the Editor of THE LANCET.

SIR,—At a workmen's delegate meeting, representing the various trades and associations of the metropolis, held at 109, Dennett's-road, Queen's-road, Peckham, S.E., on Saturday evening, July 31st, it was proposed by Mr. Kempley, seconded by Mr. Hart (engineers), and carried unanimously, that a hearty vote of thanks be accorded to Dr. Wakley, Editor of THE LANCET, for his generous gift of £1000 towards the Hospital Sunday Fund, and that the secretary be requested to forward the same, and to ask Dr. Wakley if we might reckon upon his sympathy with an organisation now being formed, having for its object the exemption of hospitals from local taxation.

I am, Sir, your very obedient servant,

Dennett's-road, S.E., Aug. 2nd, 1886. C. AMMON.

"THE INSUFFLATION OF IODOFORM INTO THE TRACHEA AFTER TRACHEOTOMY FOR DIPHTHERIA."

To the Editor of THE LANCET.

SIR,—In reply to Dr. Marshall, I beg to say that in both cases there was slight transient albuminuria. In neither was there paralysis. At the time my first patient was under treatment two children in the immediate neighbourhood were taken to hospital suffering from diphtheria. Both were operated on; one died, and the other made a protracted recovery. All three children attended the same school. At the time my second patient was under treatment I was attending two cases of diphtheria within a stone's-throw of the house; both these cases were fatal. The shortness of time during which it was necessary to keep a tube in was, I believe, in great part due to the action of the iodoform.

I am, Sir, your obedient servant,

Walterton-road, W., Aug. 2nd, 1886. GEORGE SHIRRES, M.B.

Dr. W. H. Lambart's communication should have been addressed to the editor of the journal in which the "note" referred to appeared.

Dr. Martin's communication arrived too late to be dealt with this week.

CIRCULAR CLINICAL THERMOMETERS.

To the Editor of THE LANCET.

SIR,—Having had some experience with the metallic thermometers, possibly you will not object to me stating my opinion. They would appear to me to be suitable for taking the temperature of the body when it is normal or thereabouts; but when it ranges from 102° to 105°, and that on a very cold day, they run down so rapidly that it is impossible to obtain a correct reading. What is wanted is some sort of self-registering arrangement. Above all things, I would advise purchasers to have the Kew certificate; otherwise they may occasionally find a variation of from one to two degrees.—I am, Sir, your obedient servant,

Surbiton, July, 1886. F. P. ATKINSON.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Mr. Lawson Tait, Birmingham; Prof. Hannover, Copenhagen; Mr. Jos. Smith, London; Dr. Ward Cousins, Southsea; Dr. Thurstan, Southborough; Dr. C. Ll. Jones, London; Prof. Hay, Aberdeen; Mr. W. H. Denham, Southsea; Prof. Longmore; Dr. Adam, London; Mr. A. Haviland, London; Mr. Bremridge, London; Dr. Aveling, London; Mr. N. B. NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post-offices letters addressed to initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on page 2, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed.

Advertisements are now received at all Messrs. W. H. Smith and Son's Railway Bookstalls throughout the United Kingdom and all other Advertising Agents.

Agent for the Advertising Department in France—J. ASTIER, 66, Rue Caumartin, Paris.

The Annual Address IN MEDICINE IN THE UNITED STATES, AND ITS RELATIONS TO CO-OPERATIVE INVESTIGATION.

Delivered before the British Medical Association, Wednesday, August 11th, 1886,

By JOHN S. BILLINGS, M.D., LL.D. Edin.,
SURGEON, U.S.A.

Mr. President and Gentlemen,—You all know that the representative of the American medical profession first selected by your executive committee to deliver the address in medicine to-day was the late Dr. Austin Flint, sen., of New York, whose death last March is therefore a great and direct loss to you as well as to America. Every English physician knows Dr. Flint by reputation and through his writings, but only those few of you who were so fortunate as to know him personally can fully appreciate the magnitude of the loss which the medical profession has sustained in his death. This is not the time and place to attempt to pronounce a fitting eulogium upon him and his work, and I shall therefore only say that my deep personal sorrow for his removal is mingled with sympathy for the members of this Association, who have been thus deprived of the pleasure of hearing him state in person some of the results of his long and wide experience. The loss is not a total one, it is true, since he had fortunately completed his address on "The Medicine of the Future," which has been published, and has no doubt been read by all of you; but in this case the printed page is by no means a satisfactory substitute for the spoken word.

In accepting the request with which I have been honoured by your Council, that I should attempt to take his vacant place on this occasion, it is with a full understanding of my inability to fill it that I stand before you. The request came at a time when I was hard pressed by official duties, and had neither leisure nor opportunity to undertake any special research; hence, to avoid violating one of my favourite Scotch maxims viz., "That which you do not know, tell not to anyone," it was necessary to select some subject to which I had already given consideration, and which at the same time would probably be of interest to English physicians. Reflection on these restrictions soon brought the field of selection into narrow limits, almost into "a small intercept of space of one dimension," as a mathematician would say. What is the significance of this invitation extended for the first time to a physician of another country, and that country the United States, to come to this annual gathering of the medical men of Great Britain and give the address in medicine? Does it not mean recognition of the unity of medicine, of the utility of co-operation, of the fact that we have common interests, and that the time has come when it is desirable to hear from the outlying younger branch of the family with a view to mutual pleasure and profit in the future? So it seems to me; and I propose, therefore, to call your attention briefly to some points relating to the present condition and future prospects of medicine in the United States, and to the direction in which you may reasonably hope and expect from that country in the future the most useful co-operation in the improvement of medical science and art. I believe that these must be matters of interest to you, and that I can perhaps make clear certain peculiarities which do not seem to be as generally understood on this side of the Atlantic as it is desirable that they should be to ensure sound judgment upon some of the results observed.

In the first place, permit me to call your attention to the fact that it is hardly possible to make any statements with regard to medicine in, or the medical profession of, the United States as a whole which shall be definite and at the same time distinctive—that is, which will not apply almost equally well to medicine and the medical profession in other countries. This is due to the fact that there are great differences in the organisation of the profession in different parts of America, so that what is true of one State would not be true of another; what is required as to fitness or qualification to practise in one place is not required in another; and the country covers so many parallels of latitude and meridians of longitude, making the conditions of life so diverse, and producing such differences in the prevailing diseases, that a man who is fairly qualified to practise in one section may be poorly fitted to treat the endemic diseases of another. As in painting a picture, it is best to locate and define the shadows first, and deal with the lights afterwards, let us begin by considering some of the things that American physicians complain about—in other words, some of their supposed grievances. One of these is that the profession is overcrowded; that there are too many doctors, both *in esse* and *in posse*, and that this is due to too low a standard of education, and to the want of legal restrictions as to the qualifications which shall give a man the right to practise. The feelings of some of our physicians on this subject are in full accord with those of the good old New England deacon who told the village scapegrace seeking admission, that "he thought the church was about full."

Now, what are the number and distribution of medical men in America? Statistics gathered in 1883[1] showed that in the United States and Canada there were 90,410 persons calling themselves physicians, being in the proportion of 1 to every 600 of population. In Canada alone there were 3487 physicians, or 1 to 1112 of population. If we take the figures of our last census, 1880, the proportion of physicians reported is 1 to 589 of population, or 17 per 10,000. In England and Wales, by the census of 1881, the proportion of physicians is only 5·8 per 10,000, but these figures are not properly comparable with those of the United States, because they do not include unregistered persons. If the same classes were included that are counted in the United States report, I presume that the proportion would be about 9 per 10,000, or a little more than half that in the United States. The proportion to the population of those who call themselves physicians varies greatly in different localities; thus, in Colorado there are 29·3, in Indiana 25·2, in Oregon 24·3, and in Arkansas 23·5 per 10,000; while in New Mexico there are only 6·6, in South Carolina 9·2, and in North Carolina 9·7 per 10,000. [A map of the United States was here shown, on which the proportion of persons calling themselves physicians to the population in the several States was indicated by different shades of colour.]

It is not easy to give satisfactory reasons for these differences: we can only say that they do not depend to any great extent upon local legislation. The proportion of physicians is generally lowest in the southern States lying east of the Mississippi, and highest in those regions where immigration has recently been active. If we compare, by localities, the proportion of physicians to the population with that of clergymen and lawyers, we find some curious differences. It seems that the lawyers in the United States number 12·7, while in England and Wales they are 6·6 per 10,000; but that, on the other hand, the clergymen are 14·6 in England and 12·8 in the United States per 10,000 of population. In many instances it seems that where the lawyers are most numerous the supply of clergymen is smallest. I believe that a fair proportion of physicians to population is about 1 per 1000, which is not far from the actual proportion in England; while the true proportion of practising physicians in the United States is about 1 in 750. We must admit, then, that there is, at all events, no scarcity of physicians in the United States; and, as we have over eighty medical schools at work, besides a fair proportion of medical immigrants, there is no immediate danger of any interruption to the supply.

Let us now consider the second head of the complaint—viz., that the standard of education is too low. There is ground for this, considered with reference to some localities, but not for others. I said a moment ago that a man might be fairly qualified for practice in one part of the country, and yet find himself at a loss in another. This needs a little explanation, which I can, perhaps, give most easily in connexion with a map of the United States [the lecturer here exhibited a chart]. This map, which was prepared for a

[1] Illinois State Board of Health Report, 1883.

very different purpose, indicates by different shades of colour the relative proportion of deaths reported as due to malarial disease to the total number of deaths in different parts of the country for the census-year 1879-80. You will note how comparatively light the tint is in the north and north-east, and how dark the shades become in the south and in the valley of the Mississippi, thus indicating the great differences which exist as to the prevalence and deadly effects of the malarial poison in different sections of the country. It is in some of these low bottom lands and swampy districts that we meet with cases of congestive chills and of malarial hæmaturia—cases in which the patient has been described as being "a mere appendage to a huge malarial entity, an incident of a miasmatic cataclysm." Furthermore, this strip of land bordering on the Gulf Coast is in the yellow fever zone, and has heretofore been repeatedly desolated by this pestilence.

As compared with the north and east, much of this malarious region is a thinly settled country, an almost purely agricultural country, and not a rich one. I need hardly tell you that the physician who has received his chief clinical instruction in the office of his preceptor in Vermont or New Hampshire, supplemented by distant glimpses of a few cases in hospital in Boston or New York, will find himself at a loss at first in dealing with the emergencies of daily practice in Arkansas and Mississippi. He will be subjected to influences which at times are dangerous to one who is not acclimated, and which tend to produce depression of spirits, want of energy, and bad health. He will not have free and constant access to scientific companionship, nor be stimulated by the influence of learned societies, and he cannot avail himself of the ordinary sources of amusement, education, and rest, such as art galleries, the drama, libraries, and museums, &c., which are found in the large cities. Moreover, the pecuniary reward the practitioner in many of these places can reasonably hope for is comparatively small.

Taking all these things into consideration, it is clear that if a man, after spending from six to eight years, and from £1000 to £2000 in acquiring such a general and professional education as it is now considered that a skilled physician should possess, then settles in such a region with the prospect of an average income of from £150 to £200 per year, it is not from pecuniary motives alone. There are such men in such places, men who are not only highly educated and skilled practitioners, but who are also original investigators and thinkers. It was within the limits of this malarial shadow that the foundation of modern gynæcology was laid by Marion Sims, of abdominal surgery by McDowell, Battey, and Gross, of an important part of the physiology of the nervous system by Campbell. Nevertheless, the rule holds good that malaria and science are antagonistic; the exceptions prove the rule. Nor can the inducements for highly educated physicians to settle in thinly settled localities be made stronger by any form of penal or restrictive legislation. Any attempt to fix a standard of requirements or qualifications for practice which shall be the same for such rural districts and for the large cities and manufacturing towns, must result in the adoption of what competent judges would consider so low a standard as to be ridiculous and useless. The demands are widely different, and corresponding differences exist in the sources of supply—that is, in the medical schools.

There is a class of medical schools in the United States whose object is to give the minimum amount of instruction which will enable a man to commence the practice of medicine without much danger of making such serious and glaring blunders as will be readily detected by the public. There are others schools whose aim and object are to make fairly well trained practitioners; the general character of the instruction given in these being substantially the same as that given in your English hospital medical schools. The results of such a three-years' graded course of instruction in medicine as these schools furnish depend upon the character of the material upon which they work—that is to say, upon the general preliminary education possessed by the student at the time of his matriculation. This is evidently too often defective, and only a few schools have thus far ventured to establish any standard of preliminary examination which at all approaches in its demands that which is required in England. The proverb that it does not pay to give a $5000 education to a $5 boy is clearly of American origin, and sums up a great deal of experience. You have nineteen portals of entrance to the profession, and have not found it easy to keep them all up to the standard. In America we have over eighty gates, a number of turnstiles, and a good deal of the ground is unenclosed common. Many of our physicians are more or less dissatisfied with this state of things and with the results thereof, and every year in some States efforts are made to secure legislation which it is supposed will protect the interests of the profession, though those who advocate such legislation are usually prudent enough to claim as their only motive a desire for the protection of the public.

Now, how does this free trade in medicine and the low standard of qualification or no standard at all required by law affect practitioners as individuals? To answer this we must divide the profession into several classes. In the first place, in all our cities, great and small, there is a large class of physicians who are as well educated and as thoroughly competent to practise their art as can be found in the world. They have studied both at home and abroad, have had extensive clinical training, are always supplied with the latest and best medical literature and the most improved instruments, and many of them are connected with hospitals and medical schools. Among them are found the majority of our writers and teachers, and the successful men are the survivors of a struggle in which there has been keen and incessant competition. These physicians, whose positions are fairly assured, and who, as a rule, have all the practice they desire, are not usually active leaders in movements to secure medical legislation, although they passively assent to such efforts, or at least do not oppose them; and their names may sometimes be found appended to memorials urging such legislation. They are clear-headed, shrewd, "practical" men, who know that their business interests are not specially injured by quacks and ignoramuses, rather the contrary in fact, for they are called on to repair the damage done by the quack to people who have more money than brains; and they are not inclined to risk the fate of the Mexican donkey who died of *congojas agenas*, that is, "of other people's troubles."

Then there is another large class of honest, hard-working practitioners, who rely more on what they call experience and common sense than on book learning. Many of these have obtained assured positions of respectability and usefulness, and are comparatively indifferent to medical legislation so far as their own interests are concerned. Others, however, who are not so successful, feel the competition of the local herb doctor or of the travelling quack more keenly, and have more decided views about the importance of diplomas. Among these are the young men who have not yet acquired local fame, and who are apt to become very indignant over the doings of some charlatan in the neighbourhood, or of some druggist who prescribes over his counter. These last are usually quite clear in their minds that the State ought to interfere and prevent injury to the health of the people. I have known two unsuccessful physicians who finally abandoned practice and who gave as a reason for their failure—one that "he did not know enough," and the other that "he had not the manners and tact which would inspire confidence in his patients," but such frank-speaking men are rare.

Thus far, as a rule, the efforts which have been made to secure legislation upon medical matters in America have come from the profession itself, and have been chiefly urged and recommended by physicians. The general public, and even the educated public, has shown very little interest in the matter. It does not demand protection against ignorance, but entrusts the care of its health and the lives of those who are nearest and dearest to it to almost anyone who announces himself as prepared to take charge of them. The number of those who profess to practise medicine in the United States and are not qualified to do so is undoubtedly large, though by no means so large as one might suppose after listening to the impassioned eloquence which is duly aired every year upon the subject. There are some advertising charlatans, and travelling quacks are occasionally to be met with, but they are rare. The most rigid tests of qualification in our profession in the United States are those required of candidates for admission into the medical departments of the army and navy. The standard established for these is about the same as that for the corresponding corps of the English army and navy; and of the candidates who apply, from 70 to 80 per cent. are rejected. Certainly we must admit that this percentage indicates an unsatisfactory state of things. But what evidence have we as to its results upon the health and life of the people? What shall we take as the measure of the difference of skill in physicians? The death-rate? If we compare the death-rate of the United

States with those of other civilised countries, we find that it is as low as any, with the exception of Sweden. Does a low death-rate mean better sanitary condition or more skill amongst the doctors? For the last twenty years the death-rate has been diminishing in England; the average amount of life for each person here has been increased, but I observe that the sanitarians claim this as proof of the value and importance of their efforts, and that nothing is said about its being in any way due to increase in medical skill or to improvements in medical science. Evidently this test is not a convincing one. Almost the only matter in which figures seem to demonstrate the importance of superior medical education and skill is in the statistics of deaths due to childbirth and of the results of surgical operations.

The proportion of deaths from childbirth to the number of births is decidedly greater in the rural districts than in large cities, and among the coloured than among the white population. If this difference were found only in the United States statistics, it might be accounted for by the differences in the trustworthiness of the sources from which the data are derived; but we find similar differences in England, and we must admit that these are probably largely due to the fact that in cities labour cases receive more prompt and efficient professional care than they do in the country. I need hardly call your attention to the results of antiseptic surgery, or of modern abdominal surgery, as compared with those of twenty-five years ago. Here there can be no question as to the improvement. It is well to remember in this connexion that whatever undue prolongation of disease or unnecessary mortality is due to want of skilled medical treatment, occurs mainly among the wage earners—the farmers, mechanics, salesmen, needlewomen, &c., and not among the rich, nor yet among the very poor.

Now, seeing that really efficacious legislation with regard to medical education or to the practice of medicine must, like all efficacious legislation, be substantially in accord with public opinion, since it is impossible to continue to punish for any length of time that which public opinion does not condemn; and as the great mass of the people of the United States have not as yet had such evidence as they can understand, and which would thoroughly convince them that it is to their interest to suppress quackery,—it follows that it is necessary to go slowly and to allow such evidence to accumulate.

To me it seems that the most important of the first steps to be taken in this direction is one which has already been taken in Great Britain—namely, the requirement that every death in the community shall be registered, and that in such registration satisfactory evidence shall be given as to the cause of death, sufficient at least to prove that such cause is what is known as a natural cause that is, that it is not due to crime. When it is admitted that one of the duties of government is to provide for such registration, both in the interests of life and to secure the rights of property, it follows, necessarily, that those persons whose certificates as to the cause of death are to be accepted as satisfactory evidence that there has been no foul play must present evidence that they are properly qualified to make such certificates. The principle is precisely the same as that which induces a government to provide for the examination of the medical men whom it employs in its army and navy. So far as the art of medicine is concerned, the demand has much, though by no means all, to do with regulating the quantity and quality of the supply; and there are few localities in the United States where the qualifications of the medical man are not fully up to the standard which the community is able to appreciate and is willing to pay for. In the natural order of things suffering and death are the remedies for ignorance, weakness, and vice, and the means of preventing the transmission of these characteristics to offspring. These remedies, though effectual, are drastic, and we do our best to avoid them; but perhaps it is well that the penalties cannot be done away with altogether. The laws regulating the practice of medicine in the United States are all State laws. If we were to judge only from what may be found in the statute books, assuming that all the laws contained therein are duly enforced, we should find that nearly two-thirds of the States have laws ostensibly regulating the practice of medicine within their borders. As a matter of fact, however, in over half the States which have laws on this subject no attempt is made to enforce them, and in almost all of them the possession of a diploma, no matter from what source derived, is all that is required. Of the various methods which have been tried in different States to ensure by law that physicians shall be properly qualified I will call your attention to two which are of special interest.

The first is that of Alabama, the principle of which is to organise the whole medical profession of the State, and use it as the means of regulating the qualifications of practitioners and of caring for the public health. The Medical Society of the State of Alabama with its branches, the county medical societies, thus forms a part of the machinery of the Government; it appoints boards of medical examiners, selects State and county sanitary officials, supervises the registration of vital statistics, the administration of quarantine, &c.—in short, it is the State Board of Health, and the county branches are the county boards of health. In that State the possession of a diploma does not give the right to practise, it simply enables the owner to go before the examining board. The examinations before the County Board are partly in writing, and are subject to review by the State Board, which has in some instances publicly condemned the local examinations as not sufficient. This system has now been in operation nine years, and has gradually been consolidated and improved by educating the local boards, and getting all physicians interested in it, until it is now working fairly well. Much remains to be done, and it is too soon to predict results; at present, the success of the system is largely due to the wisdom and energy of one man, who has given his whole time and labour to the work, and it remains to be seen whether the machine which he has built will work well without him.

The second system to which I will call your attention is that of the State of Illinois, which was commenced in 1877, or about the same time as that of Alabama. In Illinois anyone who presents a diploma, or licence to practise, from a legally chartered medical institution in good standing, is entitled to practise, and the State Board of Health is to decide as to what shall constitute "good standing." The Board of Health also examines all persons who do not possess satisfactory diplomas, and who nevertheless wish to practise in this State.

One of the greatest practical difficulties in the way of providing any system of State examinations in medicine in the United States is that public opinion will not support any law which can be supposed to condemn or in any way to injure homœopathic and eclectic practitioners or their schools, and hence any proposed law relating to medicine, or to the organisation of State boards of health, which does not recognise the existence of these sects will, in many States, at all events, meet with enough opposition to defeat it. In Illinois this difficulty was surmounted by the arrangement, that of the five physicians on the board one should be homœopathic and one eclectic. The Kansas law, passed last year, goes further in this direction, and provides that appointments must be so made that no school of medicine shall ever furnish a majority of the members of the board. Much to the surprise of many, the Illinois plan has worked very well, —there has been no quarrelling in the board—and the homœopathic and eclectic members seem to have upheld quite as high a standard of qualification as their fellow members. The results of the work in Illinois have been very good. A large number of ignorant charlatans have been forced to leave the State. The requirements of the board as to what shall constitute a medical college in good standing have been raised, and it has thus caused improvement in the medical schools, not only of Illinois, but of other States. Moreover, the neighbouring States have been stimulated to action, not only by the force of example, but because they received the men who had been driven out of Illinois, and found the accession an unpleasant one.

As in the case of Alabama, it is too soon to judge definitely of the results; and in Illinois, also, the satisfactory working of the system is largely due to one man—the secretary and executive officer of the board, who has given his entire time to the work. I do not by any means wish you to suppose, however, that I consider this as being a serious objection to this or any other plan, for in the building up of any organisation, or the carrying out of any system, much must always depend upon some one man.

The relations of the United States Government to medical education and to the practice of medicine are indirect only, the regulation of these matters by law being part of the police power which, under the constitution, is reserved exclusively to the individual States. The United States employs physicians in its Indian Department, in the Pension Department, in the Marine Hospital Service, and in the

medical departments of the army and navy; and it has power to regulate the practice of medicine in those territories which are not yet organised into States, and also in the district of Columbia, but thus far it has made no use of such power. The qualifications of physicians employed in the army and navy, and in the Marine Hospital Service, are determined by examinations made by boards of medical officers belonging to those services. The possession of a diploma from a respectable medical college is a prerequisite for such examination, but beyond this it does not count—that is to say, the examination is the same for the holders of all diplomas, and covers all branches of medicine. But while the relations of the general government to medical education are thus indirect, they have of late years become of very considerable practical importance, and are now exerting much influence upon medical investigations and literature. This is being effected by the museums and libraries which are now being formed under the auspices of the Government at Washington, and also to some extent by certain special investigations undertaken by the Government in the interests of preventive medicine. Of these various agencies one of the most important is the library which has been formed at Washington, under the auspices of the medical department of the army in connexion with the Army Medical Museum; both of these institutions being a part of the results of the late civil war. The museum was at first formed to illustrate military medicine and surgery, giving the results, primary and secondary, of injuries inflicted by modern weapons of warfare and of the diseases of armies in the field; in which direction the collection is unrivalled in extent and completeness. Gradually its scope has been enlarged to include illustrations of anatomy, development, and all branches of pathology and therapeutics, so that it is fast covering the whole field of medical science. In like manner, the library, which commenced in a collection of those books relating solely or especially to military medicine and surgery, which were required in the compilation of the "Medical and Surgical History of the War," has expanded into a great medical library, which is now one of the best practical working collections of the kind in the world. These collections, then, no longer appertain exclusively, or chiefly, to the business of one department, but belong to the whole profession of the United States as a body; and the department which has charge of them is managing them from this point of view. The influence of the library in stimulating research, and upon the quality of medical literature, is already very perceptible, and is destined to increase with advancing years. I think I may also venture to claim that the utility of these collections, and especially of the library, is by no means confined to the medical profession of the United States, for the catalogues and indexes which are being issued in connexion with them are of service to medical writers and teachers all over the world.

As regards investigations into the causes of disease undertaken at the expense of the general government, only a beginning has as yet been made; but it is sufficient to indicate future possibilities and probabilities. The main importance of the work of the National Board of Health, which was organised in 1879 under the stimulus of the great yellow fever epidemic of the previous year, was due to investigations upon the causes of yellow fever and diphtheria, upon the relations of soils and of water-supply to certain diseases, &c.—investigations of the same general character as those which are being prosecuted under the auspices of the Local Government Board in this country, and of the Imperial Board of Health of Germany. It is true that, owing to circumstances which I cannot here explain, the work of the National Board of Health has been stopped; but there is every probability that it will be resumed, with perhaps some change of organisation, at no distant day, and I need not dwell upon the vast importance to medical science of organised and systematic work in this direction. Similar investigations have been undertaken by State boards of health, and especially by the State Board of Health of Massachusetts; and the fact that Governmental health departments are tending to work in this direction is significant as to future co-operation from such sources. In this connexion should be mentioned the National Museum of Hygiene, which has been formed under the direction of the Medical Department of the United States Navy, which is now one of the most instructive collections of the kind in the world, and has also connected with it an excellent library and a well-equipped laboratory.

Comparative and experimental pathology is also receiving attention from the Government under the direction of the Department of Agriculture, which is doing some good work in the investigation of the diseases of our domestic animals. Our investigators are fortunately not hampered by anti-vivisection laws, and there is little danger that they ever will be, for though we have our due proportion of fanatics and seekers of notoriety who wish to emulate the British Antis-, their true motives are so well understood that they have little power to do mischief.

Of medical associations in the United States there are several classes. We have a few local societies analogous to clubs in their organisation, which own property in the form of buildings, libraries, &c., are somewhat conservative in their selection of members, and are only to be found in large cities. Of these the College of Physicians of Philadelphia is the oldest and has the largest and best library and museum; it will celebrate the hundredth anniversary of its existence next year. In New York the Academy of Medicine, and in Boston the Medical Library Association, are of the same character, and in general each large city has a similar society, although as yet they have not become fully anchored and established by the acquisition of property. The second class includes local societies devoted to specialties, such as pathology, obstetrics, &c. These also are found only in large cities, and as yet are few in number. Four of them only have published transactions. Corresponding with these are national societies devoted to specialties such as gynæcology, ophthalmology, surgery, pathology, and clinical medicine, &c. These societies meet annually, elect their own members, exercising care in the selection, and publish valuable transactions.

Another class is composed of the county medical societies, which strive to include all regular practitioners residing in their precincts. From these are sent delegates who form the State medical societies and the American Medical Association. The mode of organisation varies somewhat in the different States, but the representative principle prevails in all. Most of these societies publish transactions, and the American Medical Association now has its journal.

As to the condition of medical science and art in America, it partakes of the general progress, for the press now makes all discoveries the common property of the civilised world. The marked feature of the present epoch is the recent advance in knowledge as to the relations between micro-organisms and certain diseases, and the strong stimulus which this has given to preventive medicine. Sanitation is becoming fashionable, and if we may believe some of its votaries, it is a very simple matter to prolong the average lifetime to the scriptural, "threescore years and ten." All that is necessary is that everything shall be clean, and every person virtuous. Having learned to distinguish those diseases which can be prevented much more easily and certainly than they can be cured, we may turn them over to the sanitarian, who has his own battles to fight with ignorance and prejudice. If he succeeds, and so far as he succeeds, he will change in certain respects the work of the practitioner. The lives which are saved from cholera and typhoid, from consumption and diphtheria, and from the acute specific diseases, will, at last, be weakened and destroyed in other ways. The work of the physician will not be lessened by preventive medicine, it will simply be required more for older persons, and for another class of diseases. As sanitarians must depend upon practitioners for much of the information which is essential for their work, it follows that if preventive medicine is to become a working power, it will bring the mass of the profession into closer relations with the State than its members have held heretofore. What these relations shall be is one of the most interesting, and, at the same time, one of the most difficult, of the many problems with which we, or our successors, must deal. I have referred to some experiments on this subject which are now being tried in America, where it is much easier to make such trials than it is in an older country hampered with vested interests. Just at present, in this, as in a number of other things, our tendency is towards centralisation, both in the several States and for the whole country, and it is not improbable that we may go far on this road in the future.

I come now to the consideration of the second part of my subject—namely, the direction or manner in which we have reason to hope that medicine will be developed in the United States, and the kind of co-operation which you may reasonably expect to receive from the medical profession of that country. A marked feature of the present day, in medicine as in other things, is the tendency to

specialisation in study and in practice. But this very development of specialties, of increasing minuteness in the division of labour, increases the necessity for co-operation and in fact tends to create what we may call the specialty of co-operation. Formerly a rifle, or a watch, was made by a single workman. No two instruments were exactly alike, each piece had its own individuality and was not interchangeable, and the cost of the whole was such as to put it beyond the reach of the multitude. Now, the work on these things is greatly subdivided; one man makes only one small wheel, or spring, or pinion, and another another, each doing his work according to a uniform pattern, rapidly, perfectly, and at comparatively small cost. But, in addition to the workmen who make the individual parts, it is now necessary to have one person specially skilled in making drawings and preparing patterns, another to assemble the completed parts, and a third to test the whole after it has been put together. As the centrifugal force increases, the centripetal power must also increase. In one sense medicine, as we have it to-day, is the result of co-operation, not of deliberate, centrally planned and direct co-operation, but of natural selection from results produced by many men, often working at cross purposes and, therefore, wasting much energy, but nevertheless working, though blindly, to a common end. And it is safe to predict that in the future much of the best work will be done in the same way, by individual effort inspired by the love of science, by personal ambition, &c. But the results obtained in this way come slowly, and some things that we want can hardly be obtained by individual effort, even if we were willing to wait, hence we must look to organisation for help.

This is an age of machinery, of exchanges, of corporations—for all these correspond to one and the same fundamental idea. Men make machines to do what the individual cannot do; and they make them not only of brass and iron, but of men; for such an obvious source of power to the man or men who can master the combination is not likely to be overlooked. One result of such organisation is seen in our encyclopædic works on medicine, whether these be called dictionaries or handbooks; another in the great medical journals; another in associations which seek to wield political influence; another in the comparatively recent attempt at collective investigation of disease. With these may be classed also the attempts of Government departments to make scientific investigations, to form libraries and museums, to do things which require long continuity of effort on a definite plan in order to produce the best results. And it is by the combination of all these, with the efforts of individual workers, that substantial advance and improvement are to be effected. In this broader view of co-operation it is interesting to consider those fields of labour to which comparatively few physicians can devote themselves, because of want of time and opportunity, but whose proper working is, nevertheless, of the greatest importance to the practitioner. One of these is experimental laboratory work, and in this direction the prospect of valuable contributions from America is now exceedingly good. Some of the wisest of our most wealthy men have shown their appreciation of the responsibilities which riches entail on their possessors by seeking new channels through which to benefit their fellow-men. While the old and well-known methods of endowing hospitals and charitable institutions are not neglected, there is apparent an increasing tendency to endeavour to promote the advancement of knowledge, and especially of such knowledge as tends to the mitigation of suffering and the improvement of the race, to furnish means for the investigation of disease, to provide laboratories, and to endow medical schools, and thus place them beyond the reach of the temptations and difficulties which must always exist when such schools are dependent upon the fees of students, and are, therefore, practically commercial manufacturing establishments.

As illustrations of this tendency, I may mention the bequest of £1,400,000 by Johns Hopkins to endow, in the city of Baltimore, a university and a hospital of which the medical department is to be a special feature, to be provided with the best laboratory and other facilities for original investigation as well as for teaching; the gift of Mr. Carnegie to the Bellevue Hospital Medical School of New York in the shape of a well-equipped pathological laboratory; the presentation by Mr. Vanderbilt, and members of his family, to the College of Physicians of New York, of £200,000, to provide for that school new buildings and clinics having the best means of teaching and research, and the endowment by an unknown donor of a laboratory for the University Medical College of New York, with the sum of £20,000. Last year, in his retiring address as President of the New York Academy of Medicine, Dr. Fordyce Barker referred to this tendency to regard wealth as a trust to be used for the benefit of humanity, and after sketching the requirements of the Academy on a scale which would require an endowment of at least a million of dollars, predicted that such an endowment would be furnished by wealthy citizens of the city. I believe that he was right, and that his prediction will become history.

As the class of men who have wealth, leisure, and knowledge becomes greater, there comes an ever-increasing demand, not only for the best medical skill, for the most expert practitioner, but also for exhaustive research in every direction which promises to furnish new means for the prevention or relief of suffering, and for warding off as long as possible the inevitable end, and hence there is little reason to doubt that the examples I have named will be followed by others in the near future. With such opportunities, and under such conditions and influences, the stimulus to the young and ambitious worker is strong; we have abundance of material of this kind upon which the process of natural selection can operate, and there is little reason to doubt that the result will be substantial and valuable contributions to physiology, pathology, and therapeutics.

I have already referred to some of the work which has been undertaken by the United States Government for the benefit of medicine and of the medical profession in the formation of a library and the providing of means of assistance in bibliographical research. There is another most important means of advancing medical and sanitary science which only a government can furnish, and in which field of work England now stands pre-eminent—I refer to vital statistics. In this field the United States Government has thus far done but little, yet enough to show the great interest and value of what we have a right to hope will be done in the future by combining the work of the several States. This is one of the fields in which international co-operation is most desirable; it alone can furnish data sufficiently complete and reliable for a scientific consideration of the relations of disease to geographical and race distinctions. Geographical pathology is a very old branch of medicine, as old at least as Hippocrates, whose treatise on airs, waters, and places is justly famous. Permit me to remind you of its opening clauses. "Whoever wishes to investigate medicine properly should proceed to consider the seasons of the year, and what effects each of them produces—the winds, the qualities of the waters, the situation and exposure of the city, the character of the ground, and the mode of life of the inhabitants." Then, says the wise old Greek, "from these things he must proceed to investigate everything else." There is a breadth of view in that last sentence which is particularly satisfactory. Since the days of Hippocrates there has accumulated a vast amount of literature relating to the supposed connexion between the topographical peculiarities of different cities and countries and the diseases that prevail in them; but when the books and essays which come under the heading of "Medical Topography" are examined, it will be found that the topographical part is much more complete than the medical, which latter is mainly confined to the consideration of malarial diseases, and is vague and indefinite with regard to their relative prevalence.

Much the larger part of our really valuable information on this subject has been obtained within the last twenty-five years, as Professor Hirsch points out in the preface to the recent edition of his very valuable Handbook of Geographical and Historical Pathology, and while the contributions of the United States to this branch of medical science have been already important, I hope to be able to show you that they are probably destined to be of steadily increasing importance in the future. Considered as a body, the opportunities of the medical profession of the United States for the study of the manifold influences which can cause, modify, or prevent disease, are in some respects unequalled. As regards peculiarities of climate, soil, altitude, &c., the country is so large as to afford almost every variety of combination, so that nature may be said to be making a series of experiments on a grand scale upon the mass of humanity which is so rapidly increasing in the New World. Especially is this the case with regard to the problems of heredity as connected with the mysterious relations of

certain forms of disease to race. America is at present the great mixing bowl into which are pouring streams of human life from origins the most diverse, from regions the most remote. Black and white, red and yellow, long skulls and short skulls, Celt, Teuton, and Slav, are being brought together under similar conditions of climate, food, and occupation, thus permitting of the comparison and study of the different effects, if such exist, which result from variations in parentage under conditions of exposure to the same causes of disease. For a little time, a generation or two at least, the different streams remain pure, then there is more or less mingling, in some cases very little, in others very intimate, but always there is an opportunity of studying the races separately, as well as of investigating the results of their various mixtures.

To illustrate the possibilities in this direction, I will call your attention to some peculiarities in the distribution of deaths from certain causes in different parts of the United States, and for this purpose I shall make use of the data from our last census, taken in 1880. We have no general and uniform system of registration of births and deaths. The larger cities, and about half a dozen States, have such a system, but for much the larger portion of the country the only means which we have for determining differences in amount or causes of mortality in different localities is through the census, which is taken once in ten years. The data thus obtained with regard to deaths are imperfect, because when these are collected, only at the end of the year, about 30 per cent. of the deaths are unrecorded; and they are inaccurate, because the reports of the causes of death are not furnished by persons competent to give reliable information with regard to them. Nevertheless, these data are the best that we have, and although for a large part of the country they do not give us the actual number of deaths from any cause or set of causes, they do furnish some interesting information with regard to the relative prevalence and importance of certain causes, and suggest questions and lines for future investigation, although they do not furnish definite and scientific answers.

Take, for instance, this map of the United States, upon which, by varying shades of colour, is shown the proportion of deaths reported as due to cancer, as compared with the reported deaths from all causes. Cancer, using the term in its broadest sense, is a disease which seems to be gradually increasing in frequency among civilised nations, and, possibly, to have a tendency to increase with the advance of civilisation. In England and Wales the proportion of deaths from this cause seems to have nearly doubled within the last twenty-six years, and a similar rate of increase can be made out in certain parts of America. How far this increase is a real one, and how far it is due simply to improvement in diagnosis, is a question yet unanswered.

The mortality from cancer in the United States is proportionately greatest in the New England States, somewhat less so in New York and Pennsylvania, and it causes the least proportion of deaths in the Mississippi Valley and the South generally. The proportion of deaths from cancer in the United States is somewhat greater than it is in England; but it is not possible to make any accurate comparisons in this respect. Now, why are the shades on this map so dark in the North-east and so light in the South? In the first place, cancer is a disease the mortality from which steadily increases with advanced age, as you may see from this diagram. Hence, cancer causes a higher proportion of mortality in those localities which have the greatest proportion of population living at advanced ages, and in the United States these localities are the New England States, as you will see by this map. One deduction from this, which may perhaps not have occurred to all of you, is that a large proportion of deaths from cancer indicates, to a certain extent, that the locality in which it occurs is a healthy and long settled one, since it has probably a relatively large proportion of inhabitants, and especially females, of an advanced age. But another explanation of the peculiar shading of the cancer map is found in the relations of race to the tendency to death from this disease. The proportion of annual deaths from cancer per 100,000 living population was, in round numbers, 28 for the whites and 13 for the coloured. That is to say, cancer is more than twice as prevalent among the whites as it is among the coloured in the same localities, for these figures apply only to the South. On the other hand, cancer appears to cause a greater proportion of deaths in persons of Irish and German parentage than it does among the rest of the white population, the indications being that between the ages of fifteen and sixty-five the Germans are especially liable to cancer, more so than the Irish, and decidedly more so than the average white population. Now, when we remember that the greater part of the coloured population is in the South, and the greater part of the Irish and German population is in the North, we have another reason for the differences in mortality caused by this disease in the two sections.

Again, take this map, showing the distribution of the deaths from scarlet fever during the census year. You see that this also was most fatal in the North, and, here again, the influence of race comes in, because in the negro race the mortality from this disease appears to be very low. This disease has always been much rarer in the South than in the North, and the contrast was much stronger in former years than it is at present; but this cannot be explained solely, or even to any great extent, by difference of temperature, because scarlet fever has often been epidemic in the tropics, and, on the other hand, in many localities in temperate climates it is among the rarest of diseases.

Here is another map showing the distribution of deaths reported as due to diphtheria during the year. Diphtheria is a disease which has been unusually prevalent in the northern portion of the United States for several years. During the census year it caused 2374 deaths out of every 100,000 deaths from all causes, while in England, for the year 1880, the deaths from diphtheria were 532 per 100,000 deaths from all causes—that is to say, the comparative mortality from this disease in England was less than one-fourth that of the United States for the same period. Diphtheria, again, is essentially a disease of the North, but especially of the North-west. It causes an excessive mortality in children of German parentage, sufficiently so to show that here again the influence of race comes into the problem, although probably only indirectly—that is to say, it is probably the habits of a peculiar class of people which favour the propagation of the disease rather than any physical peculiarities in the structure of their bodies. Two more illustrations of the geographical distribution of disease in the United States may be of interest in this connexion. The first is that of consumption, the second of pneumonia.

Consumption is a vague term, and, as used in the census, no doubt includes many cases which were not true tubercular phthisis. It is reported as causing 12 per cent. of all the deaths, or more than any other single cause. In England and Wales, in 1880, it caused a little over 9 per cent. of all the deaths. Such wholesale ratios are, however, of little interest or value. There are very great differences in the liability to this disease in different parts of the United States, as the map makes sufficiently evident; and it is from a study of the causes of these differences in the data derived from large masses of people, combined with clinical histories and experimental laboratory work, that we have good reason to hope to obtain knowledge, not only of the causes of this disease, but of better methods of prevention and treatment than are now at our command. It causes a greater mortality among the Irish than in other white races, and perhaps a greater mortality among the coloured than among the white.

Next to consumption, pneumonia is reported as causing the greatest number of deaths in the United States during the census year, giving a ratio of 8·3 per cent. of all deaths, as against 4·8 per cent. in England and Wales in 1880. Here, again, the local distribution of deaths is interesting, and the contrast between the map of consumption and that of pneumonia is very striking. Here, again, we find that race peculiarity is an important factor in the problem, the proportion of deaths from pneumonia among the coloured being much greater than it is among the white.

I have elsewhere commented more fully than it is possible to do here upon these peculiarities of the distribution of certain causes of deaths in the United States.[2] In fact, my only object in calling your attention to the subject is to indicate the direction in which we may hope for good work hereafter, which indication is the chief, if not the only, valuable result of the work already done. In the brief comments which I have made upon these maps you will have noticed the stress which I have laid upon race peculiarities. These race problems are simply problems of

[2] See report on Mortality and Vital Statistics of the United States as returned at the tenth census, 2 vols. 4to, Washington, 1885-1886.

heredity taken in mass, and there is no need to urge upon an assemblage of medical practitioners the importance of considering family peculiarities in diagnosis, prognosis, and therapeutics. That the questions involved are difficult and complicated is true, but we are already possessed of more knowledge with regard to them than is commonly supposed.

In a lecture on "Life," delivered a few months ago, Professor Brookes, of the Johns Hopkins University, illustrated this as follows: "If I am placed, with my eyes bandaged, before a stone lying free on the surface and am told to kick it, and if I know at the same time the size, shape, and weight of the stone and the character of the surface, I can form a pretty accurate idea as to what the result upon the stone will be. While if the object to be kicked is a dog, and I am given precisely the same data, I cannot tell what will be the effect. But if I can see the dog, I can in many cases predict pretty accurately. If he is a bulldog he will do one thing; if he is a Gordon setter he will do another." And, in like manner, the old family doctor knows that when a particular disease appears in his neighbourhood he may expect to see it produce in one family convulsions, in another collapse, and in a third little or no danger or inconvenience. This kind of knowledge is, however, at present mainly confined to individuals, it has not become a part of the world's knowledge; it is not defined—in other words, it is not scientific. To make it so is the work of the future, and in this work I hope that we shall be able to help you.

I have spoken to little purpose if I have failed to show you that there is a great deal of human nature in American physicians, and that it is a kind of human nature with which you are tolerably familiar. It should be so, for we are of the same race, a race which, perhaps, as Emerson says, "sets a higher value on wealth, victory, and material superiority than other men, has less tranquillity, is less easily contented." Our ancestors were restless, fighters, freebooters, and from these ancestors we have the common inheritance of energy; of what *we* call "firmness," and our opponents unreasonable, pigheaded stubbornness; of liking to manage our own affairs, and, at the same time, to exercise a little judicious supervision over those of our neighbours; of hatred of humbug and lying; and, in spite of our discontent, of a firm belief that our wives and children, habits, houses, modes of business, and of treating disease are, on the whole, better than those of any other people under the sun. Privately, and between ourselves, we grumble and declare that the country and profession are going to the dogs—nay, we must do so, or we should not be of true English blood; but there is no need for me to tell you that these are only "growing pains," and not symptoms of progressive ataxy. While we must consider the difficulties in the way of the improvement of the science and art of medicine, difficulties due to ignorance, to indolence, to conflict of interests, and to the eternal fitness of things, the existence of such difficulties is not a matter to be bemoaned and lamented over. These obstacles are the spice of life, the incentives to action, the source of some of the greatest pleasures which it is given to man to experience. The child, spending a happy hour with its new puzzle is a type of the scientific investigator. The naturalist who objected to the statement that this is a miserable world which it is well to be soon done with, on the ground that there are still many species of rhizopods which he had not examined and classified, is another type. On the ethical and sociological side, the matter is summed up in Ruskin's aphorism, that "Fools were made that wise men may take care of them." It is surely not without cause that there has been given to us this restless spirit of inquisitiveness, this desire to compass the heavens and the earth, this raging, infinite thirst for knowledge; it is the outcome of brain training and natural selection for thousands and tens of thousands of years. We are in a period of the world's history characterised by material prosperity, by increase of populations, by tendencies to uniformity, to the making of individuals of small account. According to the Swiss philosopher, Alphonse de Candolle, this is to last a thousand years or so, after which the pendulum will swing the other way, and there will follow a long period of diminution and separation of peoples, and of decadence. Against that decay of nations we know of but one remedy, and that is increase of knowledge and of wisdom. And this increase must be in *our* knowledge, in the world's wisdom, and not merely in that of John, or Fritz, or Claude. As each man has special opportunities and duties, if he can only recognise them, so it is with guilds, with professions, and with nations.

I have tried to indicate to you some of these opportunities which are presenting themselves to my colleagues, your brothers, in the lands beyond the sea, and I hope that I shall not be considered rash or vainglorious in saying that I believe they will so use those opportunities as to return compound interest for what they have received from the storehouse of our common inheritance. Force changes form and place, the stored energy of the soil of our plains and valleys has been coming here in the form of meat and grain, has appeared in muscle and brain, and in a hundred other shapes, but none has been destroyed; our loss has been your gain, and in our turn we have received full and fair exchange.

It is our part now to remember that there are not two springs in the year, there are not two periods of youth abounding in energy and desire, or of manhood's strength and self-poise, in the life of any man or of any nation, and for us, as for those who have been before us, the Kanuri proverb holds true, "*Kabu datsia, kargum bago*"—The days being finished, there is no more medicine.

ABSTRACT OF

The Address in Surgery,

Delivered before the British Medical Association, Wednesday, August 11th, 1886,

By FREDERICK ABELL HUMPHRY, F.R.C.S.,
SURGEON TO THE SUSSEX COUNTY HOSPITAL.

THE MEDICAL ASPECT OF SURGERY.

AFTER a few introductory remarks Mr. Humphry said: "In former years your visits have been made to great centres of industry and great centres of intellectual and professional activity and vigour. Your visit this year is to a town probably quite as large as many at which you have held your meetings, but it is a town of a peculiar character, having no special manufacture, no definite industry of its own; it is wanting in many causes of those great surgical injuries and surgical disease that form the fruitful subject of such a paper as this. In fact, it is a town where not disease, but recovery from disease, is, medically speaking, the chief characteristic. And so, in the wards of our hospital, the numbers of serious and acute diseases do not hold the ordinary proportion to the chronic and strumous cases; hip-joint disease, necrosis, and similar affections that abound in the surrounding country districts.

"In casting about, then, for a fit subject for these remarks, I have not chosen to bring before you any group of cases from my own experience, or any special form of treatment for any special disease, but rather to take a wider and, I trust, as interesting subject for consideration. Looking back over the last half century, I suppose the greatest change that has occurred in the practice of surgery has been the development of the so-called specialties. This development is cause and consequence, too, of the enormous increase in the knowledge of the art and science of surgery that has occurred during that period.....But, while fully recognising and valuing these great and rapid advances in different directions, it may be worth while to pause—as it were to take breath—and even look back on the ground already covered. Are we going too fast? Old theories, old opinions, old treatment, old books, are they sufficiently studied and considered? Are the old relations between medicine and surgery still maintained? Is the medical side of surgery (if I may so speak) holding its ground, and making the same advances as the more strictly called surgery?

"Of late years, how much has surgery done for medicine? Has medicine done as much for surgery, and has the medical treatment of surgical disease received the same consideration, or made the same rapid strides as the study and development of operative procedure? It is now more than fifty years ago that Sir William Lawrence, in an introductory lecture at St. Bartholomew's Hospital, said: 'It is the boast of modern surgery to have greatly diminished the number of operations.'.....That improved knowledge of which Lawrence boasted, and to which he referred as the cause of lessened operations, has in itself, by the medical aids to surgery it has introduced, been the main cause of their greater frequency and of their increased success. But,

after all, the fact that, in any case, recourse is had to an operation is an admission that medical treatment has failed in curing the disease. We can hardly open an abscess without acknowledging that, by simpler means, we have been powerless to combat the inflammation that preceded it. In what state, then, is our knowledge as respects surgical medicine?

"And, first, of inflammation—that subject which occupies rightly so much space at the commencement of all surgical works, and is the enemy we have to meet at all corners in the treatment of surgical disease. It would occupy too much time here to compare the present state of our knowledge of those pathological changes comprised under the head of inflammation with what it was, say, in John Hunter's time; for, in spite of our general advancement, and with the additions of chemistry and the microscope, our views, for all essential purposes of treatment, have not been materially altered in principle. And yet the treatment of inflammatory affections has undergone considerable modification, due, no doubt, to the altered conditions of life. In bygone days a man really lived by the sweat of his brow, his occupation was a more active one, and, with fewer holidays and fewer aspirations to be rich, he spent the even tenour of his days in greater health and more comfort. But now life is a struggle; competition and the anxiety to be rich give a man anxious days and sleepless nights. His brain is used to the neglect of his body, and, when his holiday comes, he shrinks from the fatigue of its enjoyment. Illness then finds these two men in very different conditions. Instead of a man who, as formerly, would bear bleeding and active treatment, we now get a man in whom the nervous system predominates, whose digestion is out of order, and to whom sedatives and stimulants are necessary. This change has become so marked, almost so universal, that we are in considerable danger of forgetting the principles of the antiphlogistic treatment, or perhaps we are timid in putting them into practice in those cases really requiring it. We are inclined to smile at the way in which our forefathers were bled and purged because they had received some slight injury, the result of accident; and many were perhaps bled and purged too freely; but no one who has seen, not only the relief from pain, but also the relief from impending suffocation following a prompt bleeding, in the case of a man suffering severely from fractured ribs, can doubt that the principle, when properly applied, still holds good. ..... In inflammatory affections of other organs, also, we are probably becoming too timid in the use of depletion. The onset of many local inflammations may be cut short by a free and timely local bleeding. Even a strumous affection of the hip-joint will often have an inflammatory commencement, perhaps following some slight injury; if this condition be recognised sufficiently early, and be treated by the application of a few leeches in addition to the ordinary long splint, the inflammatory part of the illness may be controlled, and opportunity be given for the constitutional part of the malady to be arrested by other means. ..... In medical surgery, syphilis is one of the subjects that has necessarily received much attention. Compared with, almost classed among, the exanthemata, with its period of incubation, its local manifestations, and its subsequent constitutional symptoms, its pathology seems to have been put on a surer foundation, and the principles of treatment are consequently of a more definite character. Still, all this further experience and investigation does not invalidate in the main either the views of pathology or of treatment as laid down by John Hunter. Its further history has, however, been much extended, and a whole train of symptoms not mentioned by the older writers on syphilis have been explained as due to specific deposits; and the term 'visceral syphilis' now includes many pathological conditions that were certainly not recognised as due to this disease. In treatment, now as formerly, mercury is the one remedy—at all events, in the early stages; but salivation, formerly looked on as the necessary evidence of mercury having affected the system, and with it the constitutional disorder, is not considered necessary—indeed, is now supposed not to have so good an effect as the slower result obtained by the long-continued use of small doses. In this way the patient does not suffer from the treatment as well as from the complaint, and is able to continue any active occupation he usually follows. On the other hand, in the use of iodide of potassium for the gummata and other tertiary deposits, it would seem that the further they are removed in point of time from the primary affection, the greater the necessity for its free administration. Symptoms yielding slowly, or not at all, to small doses will, if these be quickly and largely increased, soon show signs of decided improvement..... Cancer still remains of all diseases, though unfortunately one of the most common, one of the most obscure and the most intractable. It still defies all our attempts at cure. ..... Beyond the relief from pain, medicine has, at present, proved useless. From time to time remedies have been tried, and some have held their ground for a season; but after a long experience have proved of no avail. But we should not be deterred by this failure; those who are specially working at this subject, and who are connected with hospitals for its treatment, are always open to try fairly any remedy which can show any reasonable prospect of success; and surely we may yet hope the time will come when some relief, perhaps some cure, may be found for this dire disease. M. Pasteur has recently opened a wide field for investigation of this kind; may we possibly look for any help from following the lines he has laid down in the treatment he has adopted for hydrophobia and some other diseases of the brute creation? ..... Very early removal is at present our only remedy; but surely the efforts of surgical medicine should be directed more than they have been to the medical treatment of cancer. Surgery has done much of late for its removal from regions hitherto looked on as inaccessible; how far greater the triumph, if, by remedies prophylactic or otherwise, some method of treatment could be discovered that would obviate the constant recourse to the knife, with even then a strong probability of a return of the disease. Till lately, the physician has laid claim to the three great cavities of the body as his peculiar province, but this is so no longer. The surgeon is now called on to assist in their treatment when, from the occurrence of inflammatory effusions or morbid growths, medicine is manifestly powerless; and there is now scarcely an organ that has not been attacked by the operating surgeon with a view of relieving some pathological condition. But, while the surgeon is thus intruding on the physician's province, it behoves him also to participate in the physician's knowledge; while surgery is steadily advancing by introducing new operations and perfecting old ones, is surgical medicine equally advancing by improvements in diagnosis, in its power specially of laying down definitely those indications that make such operations advisable? Surgery of this kind is of a comparatively recent date; but, to the credit of modern surgeons, it may be said that with their increased skill in operating has also increased their skill in diagnosis..... Diagnosis has, however, arrived at a very high development in determining the presence and locality of tumours in the brain, and that with sufficient accuracy to warrant the surgeon's attempt at their removal. The cases, of course, at present have been few, but sufficiently numerous and sufficiently successful to justify further trial; but with our present knowledge there are, I think, few of us who could depend on their powers of diagnosis enough to encourage them in undertaking so serious an operation..... Still, in spite of early and accurate diagnosis, in spite of advancing medical knowledge, operations are still increasing.

"Anæsthetics, and now antiseptics, have been the chief medical helps to the operating surgeon. The administration of chloroform (as a type of the anæsthetics) is now, from the natural requirements of the patient, so necessary a part of the operation, that it becomes more a matter for theoretical than practical consideration as to whether its use is attended or not by any disadvantage in the further progress of the case. The immediate gain to the patient, excluding the very few sad exceptions, is of course enormous. There can be no doubt that the introduction of antiseptics has both increased the number as well as the success of operations. Certainly, many of the large abdominal operations would not have been undertaken unless the surgeon believed that, by their use, the patient was freed from most of the casualties that follow such proceedings. Records of cases treated antiseptically show marvellous results; but of late as marvellous results are occurring in the hands of those who have relinquished that treatment. By antiseptics, I would at once say that I include those means by which septic matter is prevented from being absorbed into a wound; but while fully recognising the importance of Sir Joseph Lister's experiments with regard to the fermentative process and the resulting germs, I cannot believe that on their presence or absence depends the health or otherwise of a wound..... I must also mention here the very great advantage to hospital

surgery from the recent very laudable antiseptic *furore* among the nurses. We must all, I am sure, attach the greatest consequence to the improvement, not only in the education and the social status of our present race of nurses, but also in their great attention to the cleanliness of the patients, as well as their wounds. I would admit, then, the great gain to surgery from the use of antiseptics; but I would limit this admission to the gain from the absence of the putrefactive change, not to the absence of germs and the fermentative processes therein implied.

"Among the recent aids to surgery must be mentioned electricity. From its stimulating effects on the nervous system, it has long been used to give tone to limbs and muscles weakened by disease or injury; but of late advantage has been taken of the chemical effect produced during its passage through the tissues, and of the decomposition that ensues, to cause resolution of tumours or coagulation of blood. In this way it has proved chiefly useful in the treatment of those large thoracic aneurysms that are not amenable to other surgical relief. The clotting that takes place between the needles introduced well into the cavity of the sac becomes the focus for still further coagulation; and in this way, perhaps after repeated applications, the increase of the aneurysm has, in some few cases, been arrested, and, in several, amelioration of symptoms & delay of fatal ones has been accomplished. In nævi and small blood-tumours, electrolysis has the advantage of curing the disease with certainty, and with but little scar. Probably in medical, as in social, life, electricity has not yet fulfilled all the requirements we may expect of it. Some further development of the telephone and the electric light, in its application to medical purposes, will almost certainly take place, and large additions will, we may fairly hope, by their help, be made to our present means of surgical diagnosis.....

"Among the medical aids to the treatment of surgical disease, it would be disloyal of me, speaking in this place, and after a long residence in this town, not only to mention but to enforce the great advantage to be gained by sea air. Besides the bracing effect, as it is popularly called, of sea air, there is no doubt that many surgical diseases distinctly benefit by a sojourn here. Roughly speaking, the effect on people in health on coming to Brighton is somewhat to check the natural secretions; and, in like manner, probably, patients suffering from exhausting illnesses or discharging abscesses are certainly benefited. They not only improve in general health, bnt the discharge lessens, a sinus takes on a more vigorous action, and night-perspirations are much diminished.....

"But you will say, What is the object of these remarks—to what do they tend? Surely to this, that while great, almost marvellous, results have followed the late advances and improvements in operative surgery, and which have been so carefully and so scientifically matured by many distinguished surgeons, there is still a wide field open for the investigation and improvement in the medical treatment of surgical disease; and that, on the whole, the strictly surgical and operative treatment has received more than its share of the attention due to disease, looking at it simply from a remedial point of view. I fear we must admit that the tendency of the present day is to eradicate disease rather than to cure it. In his lectures delivered at the Royal College of Surgeons, now many years ago, Mr. Hilton almost apologised for introducing the subject of physiological and mechanical rest as a branch of what he called natural therapeutics; and yet how much has surgery benefited by the principles he enunciated? He brought great anatomical knowledge and wide surgical experience to bear on this subject of rest, and seemed really to show that there were few surgical affections that were not capable of some relief, and many of cure, if the directions he gave were scientifically carried out.

"I mention this as an example of the direction in which scientific surgery may be advanced, and to suggest that if by therapeutics the pain of a cancer can be relieved, or a hip-joint saved, other means than the purely operative demand greater attention, and acquire greater importance than has been hitherto awarded them. Another bright example may be derived from the experiments lately carried on by M. Pasteur. It may, perhaps, be thought premature to accept his discovery with regard to the treatment of hydrophobia as a scientific fact, but even now the evidence in favour of the correctness of his views is very strong, and is not in opposition to doctrines already acknowledged. He deserves all praise for the patience, assiduity, and care with which he has laboured on this subject, and endeavoured to cure one of the most painful and fatal illnesses that come under the surgeon's care. Surely these examples may encourage us to attempt more in the medical treatment of surgical disease; to endeavour to discover the first deviation from the healthy condition; and to endeavour to find for such deviation some remedy that may arrest its further progress, and obviate the necessity for those operations that have justly helped to raise British surgery to its present high position.

"In making these remarks to this Association, I cannot but remember that I am addressing a body of gentlemen who are, like myself, largely engaged in general practice, and who have opportunities of watching disease from its onset to its close, in a way impossible for the pure surgeon or the specialist. Family peculiarities, family histories, family medical secrets are known to us, and in this way we have advantages for investigating, tracing, and treating disease, that we cannot be too eager to avail ourselves of. In fact, the general practititioner is the living embodiment of that principle I wish so strongly to establish—the necessary and close connexion between medicine and surgery, a principle nobly illustrated by many of our great provincial surgeons. Our practice comprises both medicine and surgery; our medical experience out of doors is brought to bear upon our patients in the surgical wards of our hospital. Chloroform has taken away from the value of the rapid and brilliant operation. He is the most successful surgeon who is also the best physician. Surgery should get more dependent on medicine for its help. Operative surgery, from the nature of things must have a limit, and surely that limit must be nearly reached. Let the medical aspect of surgery, then, command more of your interest and attention."

ABSTRACT OF

Address in Public Medicine,

Delivered before the British Medical Association, Wednesday, August 11th, 1886,

BY E. D. MAPOTHER, M.D.,

CONSULTING MEDICAL OFFICER TO THE CITY OF DUBLIN.

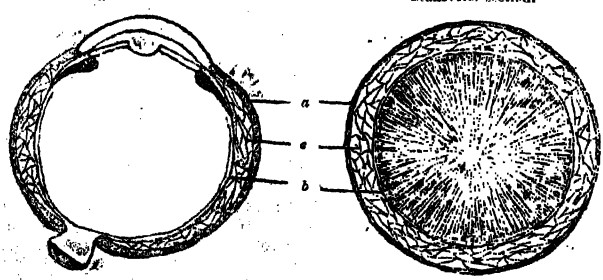
DR. MAPOTHER chose as his subject "The Medical Profession in Ireland and its Work." Referring to the Brehon code of laws, he stated that the most important of them, Senchus Mor, originated with St. Patrick; the provision in them most worthy of imitation at present was that the physicians sat in the Council of the State. They provided for distress—that is, for the support of a son taken from his mother's dead breast, and for the care of the sick and incurable. The unqualified physician was fined unless he gave notice that he was not qualified. In the sixteenth century it does not appear that the Irish were largely addicted to the use of intoxicating drinks, but in 1749, according to Dr. Rutty, there were in Dublin 3500 drink-shops in a population of about 150,000; at present among the humbler rural population alcoholic diseases are not frequent, but they are amongst the middle classes. A brief account was given of epidemic diseases which visited Ireland in past times. Ireland was spared from many mediæval plagues, on account of its insulated position, but typhus had its home in the country, and its ravages were such that during the year 1818 a million cases were recorded. During this year, Dr. Cheyne, Professor of Medicine in the School of the College of Surgeons, recorded the axilla and mouth temperature of 250 cases. At this time the profession held a high position owing to the distinguished men who practised in Dublin. It suffered heavily from typhus from 1818 to 1839, during which period 560 physicians had fever, and in 1847, 123 died from the disease. Cholera in 1866 did much mischief in Dublin, killing 923 persons; in 1867 there was a brief but fierce epidemic of cerebro-spinal meningitis. During the last six years the profession has suffered heavily in other respects; the landlords, who were formerly generous patients, have left Ireland, and the farmers and shopkeepers are becoming less able to pay fees; nevertheless, the number

of members of the profession is steadily increasing. An interesting *résumé* was then given of a paper read last year in the Academy of Medicine by Dr. Grimshaw, showing the condition of health of the Irish people. In rural districts, the average death-rate was 16·6, in urban districts 22·5 per 1000 living. The deaths from phthisis were 2·8 per 1000 among the civic and 1·6 amongst the rural population. Preventable ills in Dublin promote phthisis, but its low level and climate must also be blamed. The sick poor are better cared for in Ireland than in any other country, and this is due to the Medical Charities Act of 1851. The speaker entered in some detail into the Poor-law administration of the country, speaking of it in complimentary terms, and stating that provident dispensaries are unknown in Ireland, except in a few towns. The county hospitals were formerly a great disgrace to the country, but are now efficiently and economically managed. The clinical hospitals of Dublin are now the subject of investigation by a Government Commission. Ireland has only had a system of registration of deaths since 1864, although this system existed in England twenty years previously. Reference was made to the public medical services, and those of the army and navy were discussed at some length, and it was noted that the work of many Dublin chemists was inexact and untrustworthy. Veterinary surgery is not even taught in Ireland, and Dr. Mapother commented upon this in view of the interest of the Irish population in the production of horses and cattle. In conclusion, an account was given of the system of medical education in Dublin, and of the various licensing bodies.

ON A SPONGY FORMATION BETWEEN THE SCLEROTIC AND CHOROID COAT IN NEW-BORN CHILDREN.

BY PROFESSOR ADOLPH HANNOVER, M.D.

AMONGST the great number of eyes of new-born children which I have examined, I have four times found a formation between the sclerotic and choroid, which, as far as I know, has not been noticed hitherto. I consider this formation to be spongy, on account of the structure it presented to view when the eyes were hardened in dilute chromic acid.

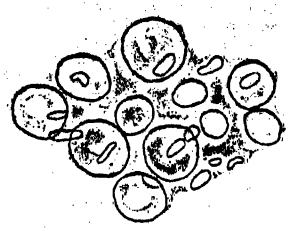


Eye of a child between one and two years of age, hardened in dilute chromic acid.

FIG. 1.

Longitudinal section.

FIG. 2.



Transverse section.

a, Sclerotic. *b*, Choroid. *c*, Spongy substance between these two coats. Double size.

(See Figs. 1 and 2.) It consisted then of small areolæ, which were elongated, flat, generally parallel to the concavity of the eye, or irregular and angular like those of the spongy substance of the penis. In different subjects this layer between the sclerotic and choroid varied from 0·5 mm. to 1·5 mm.; it was thickest at the equator of the eye, and became thinner at the back part of the eye near the entrance of the optic nerve, and likewise at the fore part outside the corpus ciliare. The membranes which formed the framework were semi-transparent and firmly adherent to the sclerotic and choroid, so that they could not be removed without injury. Under the microscope they appeared as membranes of uniform transparent structure or covered with molecules; the lines on them were caused by folds. There was, besides, a great number of round or oval clear cells, with sharp linear contours, but without any contents (see Fig. 3); even the presence of a nucleus was doubtful, although there were many bodies of their appearance on the membranes, and some of them may have had

FIG. 3.

their place in the interior of the cells. There was no connective tissue; the cells may possibly have belonged to the lamina supra-choroidea. The circumstance that the formation was always found to have the same shape and extension in both the eyes of the child made it very probable that one and the same cause had prevailed in producing it. As such a one we may most likely presume an increased secretion of the serous or rather half-gelatinous substance, which under ordinary circumstances always exists between the sclerotic and the choroid of the new-born child. The adhesion of this half-gelatinous substance, wherein the ciliary nerves and vessels rest, is stronger with the sclerotic than with the choroid; it is stronger in the posterior part than in the anterior, and stronger in the inner than on the outer half of the eye.[1] When examined with the microscope, this substance is seen to be composed of a uniform basis without any structure, intermixed with a great number of oval, angular, or pointed nuclei of different size, from which also fibres may proceed. There seems, besides, to be a faint indication of connective tissue in bundles which cross each other, and of some elastic fibres, but these may belong to the lamina supra-choroidea. (See Fig. 4.) When an eye of a new-born child is kept in dilute chromic acid for some days, the half-gelatinous substance becomes more like a fine membrane, but the microscopical relations remain the same as in the fresh state of the eyes. This spongy substance which I have mentioned has nothing to do with the lamina fusca on the inside of the sclerotica. The lamina fusca does not form a complete membrane, but consists only of bundles of connective tissue interwoven with irregular pigmentary cells, and connected with the lamina supra-choroidea by strings.

FIG. 4.

It is most convenient for the examination of the relations between the sclerotic and the choroid to wash off all the pigment from the inside of the latter, so that this coat appears almost white and without colour, except in the neighbourhood of the entrance of the optic nerve, where a light red-brown colour remains, especially extending outwards (tapetum?), caused by a brown sprinkling, but not by regular pigmentary cells. The posterior part of the choroid is not yet provided with pigment, but has only a light-brown colour—hence the reddish colour of the pupil in the new-born child. A transverse oval is formed with an excentric white spot for the entrance of the optic nerve. On the contrary, the place of the foramen cæcum is black,

[1] I have found exactly the same relation in the connective tissue between the sclerotic and choroid in the ox.

but not so dark as the rest of the choroid. The pigmentation proceeds both from the foramen cæcum and from the periphery of the oval, beginning in the foremost part of the eye and extending backwards.

The first eyes in which I discovered this formation were those of a child of between one and two years of age. The dimensions of each eye were as follows:—Vertical diameter 19 mm., transverse diameter 20 mm., antero-posterior diameter 18·5 mm. (the eyes were compressed from before backwards), diameter of the base of the cornea 10 mm. and 11·5 mm. All other parts of the eyes were perfectly normal, the radial structure of the vitreous body, like the structure of an orange, being very distinct. Nothing is known about the power of sight of the eyes.

When I had communicated the results of my observations, Dr. Paul Haensell of Paris suggested the opinion that the spongy layer between the sclerotic and the choroid might be due to an arrest of development. This hint may lead to further investigations of the eyes of the human fœtus at different ages before birth, kept for some time in dilute chromic acid in order to preserve the shape of the eyes and the possibly existing space between the sclerotic and the choroid.

Copenhagen.

ON A CASE OF CARDIAC DILATATION.

By GRAHAM STEELL, M.D.,

ASSISTANT-PHYSICIAN TO THE MANCHESTER ROYAL INFIRMARY.

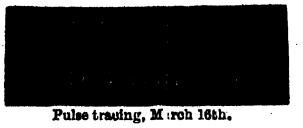
THE following case seems to me of sufficient interest to be recorded as furnishing a good example of a form of heart disease which, though comparatively rare, is important from the readiness with which, while yet in an early stage, it yields to treatment. It would seem to depend on failure of the muscle of the heart, whereby dilatation and mitral incompetence are induced. I have met with it most commonly in vigorous, muscular men below forty years of age. Most of its subjects have been exposed to the bad effects of alcoholic excess and undue strain thrown upon their heart by one cause or another; probably there is some congenital or acquired predisposition to the disease. In a fatal case lately under my care, in which the diagnosis was verified by post-mortem examination, the valves being quite normal in structure, no cause could be ascertained either during life or after death.

The diagnostic points of this form of cardiac dilatation are briefly as follows:—

1. The absence of a history of rheumatism.

2. Evidence of enlargement of the heart, affecting both sides, but especially the left ventricle, accompanied by extremely feeble cardiac impulse, the apex-beat (the impulse of the left ventricle) being especially weak and diffused.

3. An apex systolic murmur not carried backwards behind the mid-axillary line, accompanied usually by a first sound, which sound may be heard alone at the back and behind the line named.



4. The ordinary circulatory phenomena of mitral disease of the heart, such as pulmonary congestion, enlarged liver, and anasarca spreading from below upwards, along with their respective symptoms, dyspnœa, &c.

The valvular lesion with which this variety of cardiac dilatation is most likely to be confused is mitral stenosis. Certain cases of mitral stenosis have no history of rheumatism, and present a systolic apex murmur having the attributes of the murmur described above, while there is no presystolic or diastolic murmur. Even in such cases, however, there are peculiarities which will prevent confusion with the cases of which the present is an example.

The restoration of the circulation on the recovery of the heart is strikingly illustrated by the accompanying sphygmograms, taken before and after treatment. As further evidence of the recovery of the heart in the same case may be mentioned the diuresis and the disappearance of the murmur, dyspnœa, and practically all symptoms. For the notes of the case and the sphygmograms I am indebted to Mr. Mumford, house-physician, Royal Infirmary.

H. S——, a baker, aged thirty-five, has been much exposed to changes in temperature, but has not suffered from rheumatic fever, rheumatism, or colds; he has never before had a day's illness that he can remember. He has indulged in beer, occasionally taking three or four pints a day, but generally not more than two; never takes spirits; no history of syphilis. His work necessitates carrying heavy sacks of flour up to 280 lb. in weight. Father very healthy, aged sixty; mother died of dropsy, apparently cardiac, as she suffered for six months from great dyspnœa, and had to be propped up in bed; she appears not to have suffered from rheumatism; brothers and sister healthy; the patient has a family of nine children, all living and well. On March 2nd, 1886, the patient went to his work as usual, but was unable to continue at it, on account of breathlessness and severe generalised pain all over the front of the chest on both sides, which prevented him from stooping. He endeavoured to continue his work on this and on the following day, but was obliged to go home and rest. The dyspnœa came on if he only walked slowly for twenty yards. He had severe cough and swelling of the legs and face. He remained at home, sitting up in the daytime, till March 15th, when he was admitted to the Manchester Royal Infirmary.

The patient's condition on admission may be briefly described as follows: He is a large, powerfully built man of pale complexion. He complains of pain in his chest and swelling of his feet. The ordinary signs of bronchitis distributed generally over the lungs are audible on examination of the chest. The cardiac dulness is increased and extends to the left of the nipple over an inch, while the apex-beat, although in its normal intercostal space, is displaced to the left of the mammary line and is very weak and ill-defined. A systolic murmur is heard at the apex and for some distance above the apex, being especially loud at a point midway between the nipple and left border of the sternum. The murmur is accompanied by a first sound possessing a peculiar clang. A pronounced difference between the pulmonary and aortic second sounds cannot be ascertained. There is no albumen in the urine. He was ordered the following mixture: Tincture of squill, one drachm; aromatic spirit of ammonia, one ounce; infusion of digitalis, six ounces; infusion of senega, to twelve ounces; one ounce to be taken three times a day.

Pulse tracing, March 16th.

March 21th.—Digitalis mixture stopped yesterday, and a mixture containing aromatic spirit of ammonia and infusion of senega substituted. Pulse 60. "The patient is a great deal

Pulse tracing, March 21th.

better, and the cough has almost entirely gone; the dropsy has almost disappeared, and there is no pain in the chest." The murmur has greatly diminished in intensity, and is only occasionally heard.

30th.—"The patient is much better, and gets up during a great part of the day. There is no dropsy, pain, or cough." A slight diminution of cardiac dulness seems perceptible. A tracing taken to-day presents similar characters to the last one, but the tidal wave is less pronounced.

April 6th.—No murmur is audible to-day, and the first sound has entirely lost its abnormal clang. The apex-beat is now well defined and of good strength. It is situated to the left of the mammary line in the fifth space. The patient has entirely lost his dyspnœa, pain, and dropsy.

The following quantities of urine were passed:—

* Digitalis stopped.

The patient on leaving the infirmary went to the Convalescent Hospital, and after a sojourn of a few weeks there,

again attended the infirmary as an out-patient for a considerable time. While under observation he remained well, although he did not resume the hard labour to which he had formerly been exposed.

A CASE OF

INTESTINAL OBSTRUCTION RELIEVED BY LIBERATING THE OMENTUM FROM AN OMENTAL HERNIA.

BY F. A. SOUTHAM, M.B. OXON., F.R.C.S.,

ASSISTANT-SURGEON TO THE MANCHESTER ROYAL INFIRMARY AND SURGEON TO THE CLINICAL HOSPITAL FOR WOMEN AND CHILDREN.

A FEW years ago the question was discussed in the columns of THE LANCET by Mr. Holmes' and Mr. Rushton Parker[2] as to the reality of the occurrence of symptoms of strangulation in hernia containing omentum only, and the cause of such symptoms when present.

Mr. Holmes is of opinion that strangulation of the omentum only may produce symptoms identical in kind with those of strangulated bowel, though probably not so severe, and suggests that the function of the intestine is suspended by some reflex action originating in the nerves of the strangulated omentum. Mr. Parker, on the other hand, believes that there can be no such thing as symptoms of intestinal obstruction brought about solely by constriction of omentum, and that when present they are due either to dragging of the omentum on the colon ("strangulation by kinking") or to peritonitis, whether resulting from inflamed omentum or otherwise. In other cases he suggests that possibly a small knuckle of strangulated bowel was reduced previous to operation, and the relief to the symptoms afforded by operation is therefore erroneously assigned to the reduction of the omentum alone. Mr. Treves, in his valuable work on Intestinal Obstruction (p. 29) has shown that when a portion of omentum has become adherent (as so often happens when it is involved in a hernial sac), it tends to become elongated, while the rolling movements of the bowels around it help to mould it into a rounded cord-like ligament. It seems not unlikely that an omental band of this kind may in some instances drag upon and produce kinking of the colon in the way Mr. Parker suggests, while in others it may strangulate or constrict some other portion of the intestine, just as frequently happens with other bands, and in this manner produce all the symptoms of complete obstruction.

In the following case, which recently came under my notice, well-marked symptoms of acute obstruction suddenly appeared in a person suffering from a purely omental hernia of long standing, without any evidences of congestion or inflammation being found in the hernia itself to account for them, and the symptoms were at once relieved on liberating the omentum from the hernial sac.

The patient was a female, fifty-two years of age, who for some time had suffered from a small irreducible femoral hernia, and had occasionally been under treatment for dyspepsia, colic, &c. About 3 A.M. on May 3rd, having gone to bed quite well, with the exception that for a few days the bowels had been somewhat constipated, she awoke with severe colicky pains in the abdomen, which were not relieved by an emetic administered by the patient herself, as had happened on several previous attacks of a similar nature. The same evening Mr. Gowland of Hulme saw her for the first time, and found her suffering from severe paroxysms of pain in the abdomen, which was distended, tympanitic, and somewhat tender. She was put on milk diet, morphia was administered every four hours, and turpentine stupes applied to the abdomen. The following evening severe sickness set in, and continued during the night. The next morning the vomiting was becoming stercoraceous. As there had been no action of the bowels for three days, a soap-and-water enema was administered; this was followed by the passage of some flatus and a few small particles of fæcal matter. As the symptoms continued unrelieved, Mr. Gowland suggested operative interference, and I saw the patient in consultation with him the same afternoon. She was then extremely collapsed; the pulse (130) was so weak and fluttering as to be almost imperceptible; the vomiting was distinctly fæcal; there was no marked distension of the abdomen, but severe pain was complained of in the umbilical region, with tenderness on pressure; beyond an indefinite fulness just above Poupart's ligament on the right, nothing abnormal could be detected in the abdomen. On the same side there was a femoral hernia the size of a walnut; it was not tender on pressure, but felt soft and irregular, evidently consisting of omentum, and being quite irreducible. Under the circumstances, as the symptoms of obstruction were so well marked, it was thought advisable to explore the hernia, for though it was clear that it was mainly omental, it appeared very probable that a small knuckle of bowel would be found tightly nipped at the neck of the sac. Herniotomy was accordingly performed. On opening the sac, a few drops of clear fluid escaped, and a small piece of indurated omentum, quite healthy and free from any signs of congestion or inflammation, was found in its interior. Its pedicle, which was about the size of a lead-pencil, completely filled the neck of the sac, to which it was fixed all round by old adhesions, there being no room left for any bowel to have made its way by the side of it. The adhesions having been broken down with the finger and a director, the pedicle was drawn down and surrounded high up with a catgut ligature, and, after the omentum had been removed on the distal side of the ligature, allowed to slip back into the abdominal cavity. The sac itself was then removed, its neck having been secured by another ligature. On recovering from the anæsthesia the patient at once expressed great relief from the operation, the abdominal pain having quite disappeared. There was no recurrence of the sickness, and henceforth all went well with the exception of a troublesome diarrhœa, which set in the following evening and continued for some days.

The sudden onset with the acute nature of the symptoms in this case, and their complete disappearance immediately the omentum was set free, point either to strangulation by kinking of the colon, or to constriction of some other portion of the bowel, probably of the small intestine, by an omental band, continuous with the pedicle of the portion of omentum present in the hernial sac.

Manchester.

CASE OF CÆSAREAN SECTION IN COUNTRY PRACTICE; RECOVERY.

BY THOMPSON FORSTER, M.R.C.S., L.S.A.

ON May 16th, 1886, a man came to me at 10.30 P.M., stating that his wife was in labour and the midwife said there was something wrong, "the child was crossed." He was in great distress.

The patient, aged twenty-three, married, primipara, had been very delicate all her life, and subject to fits and very frequent sickness; she had been in labour during the whole of the 15th, and suffered severe pains on the 16th. The membranes ruptured at midday. She was in the following condition: Head presenting; os fully dilated, but the head had not in any way entered the pelvis; pelvis contracted; upper part of sacrum projecting. I considered it impossible to deliver the child entire. The cottage was so small, so badly ventilated, and the surroundings so unsatisfactory, that I decided to open the head, and endeavour to remove the child. I called in my friend, Mr. Johnson, who entirely agreed with me, and undertook to administer chloroform. Having opened the head, from which no blood flowed, I concluded the child was dead before commencing. Every effort was used to bring down the child's head, but without success. I could not introduce my hand. We agreed that delivery per vaginam was quite impossible. We then decided upon the Cæsarean section. I made the following arrangements: placed the woman across the bed, the nurse to take charge of the patient's hands, Mr. Johnson to see to the chloroform, one farthing candle on the bed and one on a chair with a basin of water and sponges, and one small petroleum lamp on a box with the instruments. I could not get further assistance, as the friends would not come into the room; if they had, they could not have moved. As soon as she was ready and well under the influence of chloroform, which she took freely, I made an incision through the skin and the peritoneum at the upper part, and passed two fingers

[1] THE LANCET, vol. ii., 1883, p. 21. [2] Ibid., vol. ii., 1884, p. 211.

into the cavity as a guide, and extended the incision down to the pubis, about five inches. There was no more room. The uterus presented. I opened it freely, and the back of the child presented. With some difficulty I drew out the empty head, which I found the easiest, and removed the child, which weighed 9½ lb., and divided the cord. Then the placenta presented; this was removed easily, being free, and apparently floating in blood. As soon as it was removed blood poured out over everything. I then took hold of the fundus of the uterus with my left hand, and compressed the neck with my right. I then left the neck, as it was flabby and long, and the os very flabby, though the fundus was getting firmer, and began to sponge freely, still holding the fundus very firmly in the left hand. The bleeding slackened, but on removing my hand the blood flowed out as fast as ever. I applied the sponge freely, and then squeezed it out in cold water and pushed it into the uterus, holding the uterus with both hands. The bleeding then ceased. During the whole of this time the woman was vomiting violently, and forced down a large piece of omentum and some of the small intestines, which were violently projected through the wound. These were passed back steadily but very firmly, and held for a short time until the vomiting had slackened. I then carefully sponged out all the blood until the whole was quite dry and free from blood and water. The edges of the uterine wound were everted. I then perceived a faint odour of urine, so I examined the bladder, which was sound and almost empty. The vomiting began again a little, so I had to hold the intestines in with the back of my left hand whilst I passed in three deep sutures through the peritoneum of strong silver wire and twisted each one as I passed it, also twisting three small vessels. This was necessary because of some restlessness of the legs, which made it a little difficult. I then passed two shallow sutures of the same wire, and placed a piece of dry lint on the wound, and a thick pad of Strutt's absorbent cotton put on firmly, and a flannel bandage.[1] I found the bed so saturated with blood that I had to get a bag of straw that some children were sleeping upon in the room above, and removed the wet one and put the patient on this. I then put her on a man's old shirt, and covered her with two blankets; there were no sheets or other blankets at hand. I gave her a one-grain pill of capsicum and camphor, to be repeated every four hours, and left her in the care of her mother, the midwife going home. The difficulties having been all overcome by time and patience, I left the woman at about 4.30 A.M., comfortable as far as possible.

May 17th: Some pain. Passed urine freely; some bloody discharge with it. Pulse 120.—18th: Pulse 120; temperature 102·5°. Sweating very freely; to continue opium, and give beef-tea, milk-and-water, and barley-water as required. Dressings dry, excepting from the sweat, which saturated them; passed urine freely.—19th, 10 A.M.: Temperature 101·2°; fresh flannel bandage over the old one to tighten it; some flatulency; passed urine freely; back tender from the rough ticking and hard bed; abdomen tender; put a bag of powdered sulphur over the abdomen, and some over the bed and patient; to continue support; omit opium; some bloody discharge per vaginam.—20th, 10 A.M.: Pulse 120; temperature 102°; patient comfortable and very thirsty.—21st, 10 A.M.: Pulse 120; temperature 101°; patient comfortable.—23rd, 10 A.M.: Pulse 100; temperature 100°. Mother obliged to go for the day; bowels acted slightly.—25th, 10 A.M.: Pulse 110; temperature 102°; bowels irritable. Nurse removed some hard masses of fæcal matter, and then the bowels acted very freely.—7 P.M.: Very comfortable. Removed dressings and sutures; wound quite dry, and not even a pink blush, but apparently healed by first intention. Dressed with adhesive plaster and flannel bandage.—26th, 10 A.M.: Very comfortable. 7 P.M.: The nurse had gone home, as the mother came to say she could not stop, and must go home. There was some difficulty in getting a nurse. The patient cried all the afternoon. She had a fit of vomiting. Ordered brandy and one grain of opium every four hours. A drop of pus came from the suture hole.—27th: Temperature 104°. I dressed the wound, which had opened, I suppose, from the retching, and breathing quick and irritable. 7 P.M.: Delirious. Pulse 140; temperature 105°. Dressed the wound with sulphurous acid, 9 per cent., one part to four of water.—28th: Delirious all night. Sulphurous acid, twenty minims, 9 per cent., water one ounce, every three hours. Teeth dry; tongue dry; temperature 104°; frequent cough and expectoration.—29th: Temperature 102°. Bedsore on back. Cough and some diarrhœa.—31st: Temperature 105°. Diarrhœa severe. Lead and opium pill (five grains) every four hours. Some discharge per vaginam.

June 1st: Temperature 100°. Diarrhœa stopped. No medicine.—2nd: Removed to airy, comfortable lodgings. Since May 27th I have dressed the wound with sulphurous acid, 9 per cent., one part acid to four of water. Discharge very free, as of an ordinary period.—6th: Temperature 98·5°. Discharge very free. Ordered mutton chops and porter. There has been only four drops of pus during the whole time.—7th: Discharge ceased almost entirely. Wound healed. Gets up to night-stool, as the bedsore is so painful and large that she cannot use the bedpan. No ill effects.—18th: Walked home. Bedsore still large.—20th: Met the woman walking in the streets on her husband's arm, having returned to household duties.

Daventry.

[1] Sir Spencer Wells advised some years ago the necessity of dry sponging.

A Mirror OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

CHARING-CROSS HOSPITAL.

STRICTURE OF THE ŒSOPHAGUS; GASTROSTOMY; RECOVERY.

(Under the care of Mr. RICHARD BARWELL.)

THE following case of gastrostomy, which was performed in the manner which now finds most general acceptance, at two operations, as recommended by Mr. Howse, will be read with interest. In it the stomach was not opened and food introduced until five days after it had been secured to the abdominal wall, when adhesion was firm. In cases of cancerous stricture of the œsophagus it is always a serious question as to whether gastrostomy should be performed or not, and if the operation be decided upon, as to the time for its performance. In a paper published not long ago by Dr. Hacher it is stated that Professor Billroth is of opinion that the operation should not be undertaken until the swallowing of fluids is quite impossible. This view would hardly meet with acceptance with British surgeons, most of whom are in favour of doing it at an earlier date, before the patient is so much reduced in strength by starvation as to make any operation of importance and risk to life, *a fortiori*, one in which the peritoneum is exposed and manipulated. The case which is appended, in which the operation was performed before complete obstruction had taken place, not only gave the patient great relief, but enabled her to return to her ordinary occupation, and has undoubtedly considerably prolonged life.

Eliza C——, aged forty-six, was admitted into the Golding ward on Feb. 3rd, 1886, on account of difficulty in swallowing, which necessitated many efforts, but still did not absolutely preclude deglutition. After thorough exploration of the chest, a bougie three-eighths of an inch in diameter was passed without difficulty for ten inches from the upper dental arch, but here decided resistance was encountered. Smaller and smaller instruments were gently used, and it was found that a No. 12 catheter could be got through the stricture without force. As there was no history of traumatism, it was evident that the stricture must be either syphilitic or malignant. No sign or history of the former could be found, nevertheless iodide of potassium was given, and its effects carefully watched. No instrumental treatment was deemed advisable, and the patient desired to be treated outside. She did not improve under the iodide, and in a fortnight it was discontinued. After another fortnight the difficulty of swallowing became greater, the efforts more painful, and she also began to lose flesh. Again, in another

fortnight she was evidently worse, had lost 14 lb. in weight during the past month. Her condition and the effect of gastrostomy were explained to her, and she urgently desired that the operation might be performed, in order to obviate the pain and trouble of attempting to swallow. She re-entered the hospital early in April, and on the 13th Mr. Barwell performed the first stage of gastrostomy, making an incision, three and a half inches long, three-quarters of an inch below the margin of the costal cartilages, commencing about the same distance from the middle line. The abdominal wall was opened through the fibres of the rectus, because it seemed desirable (the stricture being so low) to avoid going very near the cardiac end of the stomach. The viscus was found narrow and contracted, but it was easily drawn down with the fingers from behind the liver, and was sewn in two circles to the abdominal wall, the wound through which was then stitched. She was ordered to be fed per rectum.

April 18th.—No pyrexia of any kind or discomfort followed the operation; and at this date Mr. Barwell punctured the stomach at the opening with a tenotome and introduced slowly, so as to stretch the puncture, a glass tube with a conical end. An indiarubber tube was attached to this, and she was ordered to have two ounces of liquid food every three hours. Feeding per rectum to be continued.

24th.—The amount of food taken by the stomach has been gradually increased, the feeding per rectum diminished *pari passu*; it was at this date discontinued.

May 1st.—Patient takes food into the mouth and ejects it thence, after mastication, into the funnel connected with the indiarubber tube. Four days ago she was allowed to get up, was very comfortable save that some irritation around the wound resulted from a slight overflow of gastric juice.

12th.—Patient went out at her own request, being very comfortable.

July 24th.—During this month she has returned twice to report herself. She is well and gaining in flesh.

PRESBYTERIAN EYE AND EAR CHARITY HOSPITAL, BALTIMORE, U.S.A.

A CASE OF CATARACT.

(Under the care of Dr. JULIAN J. CHISOLM.)

D. S——, aged fifty-two, a finely developed man, in apparently perfect health, has a cataract fully formed in the left eye, and one also forming in the right. The left eye has been blind for two years. Light perception is good in this eye. He can get about readily by means of the right eye. The left lens was removed under the local action of a 4 per cent. solution of the muriate of cocaine. It was a mixed lens, with small nucleus and much cortical matter. When the pupil was cleared of lens detritus he counted fingers with this eye. The surface of the eye was carefully sponged with a solution of the biniodide of mercury, 1 part in 20,000. A few drops of a 1 per cent. solution of the sulphate of atropia was instilled into the eye and the lids then gently closed. A piece of isinglass plaster, that which is spread on silk, light in colour and therefore diaphanous, 2¼ in. long and 1¼ in. wide, was dipped in water, and as soon as it became thoroughly pliant it was laid upon the closed lids, extending from the brow to the cheek. By the use of a rubber spoon this softened strap was thoroughly adjusted to all the irregularities of the lid surface, until it became an additional skin extending smoothly from canthus to canthus over the whole lid and contiguous surfaces. In a very few minutes evaporation dried it. It then stuck so firmly that there was no fear of displacement. The patient, with both eyes closed in this manner, went from the operating table and walked to his room, ascending often two flights of steps before reaching his bed. All the rooms of the hospital have blue shades covering the large windows, so that the light of the room is subdued; it is not so dark as to prevent reading. The hour for operating is from 2 to 4 P.M. The patient is put to bed, and allowed supper if he wishes it. No restrictions are placed upon diet; whatever he knows does not disagree is allowed to be eaten. No instructions are given as to movements. If the patient be restless at bedtime, a mixture of chloral and bromides is administered.

Second day.—The patient had some discomfort in the eye during the night, but not enough to prevent sleep. He had not taken the sleeping mixture, not needing it. The light of the room does not annoy him. It enables one to see that the plasters have not been disturbed. If there had been any watering it has evaporated, for the adhesive strips are dry. The eyes are perfectly comfortable. The patient had been up to stool, and suffered no inconvenience from it in the eye. As he seemed in every way well, no treatment was needed.

Third day.—He has had no trouble whatever. Has had a good night, and no pain at any time. One eye feels as comfortable as the other. No treatment necessary.

Fourth day.—The patient has had no discomfort during the last twenty-four hours. The adhesive straps are a little wrinkled at the lash border, apparently from some eye secretion. As there are no complaints, and as the straps on each eye are in a similar condition with no detachment of the straps, they are not disturbed. No treatment is ordered. A few drops of a 1 per cent. atropia solution are put at the inner canthus. It is seen to be drawn in under the adhesive strap in the line of the lashes, and is felt in the eye. Only a few drops of the atropia solution were used, not enough to wet the bandage, excepting the line indicated, and therefore not enough to disturb the adhesion of the plaster to the surface of the eyelids.

Fifth day.—He feels perfectly well in every way. Slept well, and has had no eye uneasiness. The adhesive plasters look moist at the palpebral split on each eye. There is every reason to believe that the corneal wound has perfectly healed, and that the plasters are no longer required. When removed the eyelashes were found a little gummy, and were cleansed with warm water. When both eyes are fully opened, they stand the light of the room equally well. There is no watering of either eye. Light does not seem in any way disagreeable. There is very little hyperæmia of the eye operated upon. A few drops of a 1 per cent. atropia solution are put in the eyes, and they are left in the moderate light of the room without protection.

Sixth day.—He has suffered no inconvenience from the removal of the adhesive straps. He is dressed, and is walking about his room with the hall-door opened. He feels well; says that his sight has grown stronger since yesterday. The eyes seem strong and show no photophobia or lacrymation. No treatment.

Seventh day.—The patient is doing well. A more thorough examination of the eye is to be made to-day. The shade was rolled up, allowing strong light to enter the room. The eye shows no discomfort from the exposure. The hyperæmia of the conjunctiva is very trivial. The pupil is large and clear, an evidence of no trouble whatever. After the examination the shade is drawn down again. A drop of atropia solution is instilled into the eye; the only treatment needed.

Eighth day. Patient strolling about the halls, feeling no inconvenience from the light.

Ninth day.—The patient was found writing in a contiguous room. He faces the open window and looks out into the sunny street without discomfort, and feels quite ready to take care of himself.

Tenth day. He sees well, and feels that he no longer needs the protection of hospital treatment. He is advised on going out to wear smoked glasses when out of doors, but not to wear them in the house; also not to expose himself needlessly to strong light.

Remarks by Dr. CHISOLM.—An item of much interest is found in the new method of dressing eyes after cataract extraction, and the manner of treating such cases in the Presbyterian Eye and Ear Hospital. It is directly at variance with the generally established and at present universally adopted method of using compressors, retentive bandages, cold water applications, dark rooms, and smoked shade glasses. The foundation for this new treatment is based upon the belief that as the cataractous eye is not annoyed by moderate light, the closed lids are a sufficient protective substitute when the lens is removed; and that when cataract extractions are treated with closed lids in light rooms neither lacrymation nor photophobia is produced, even when strong light is finally admitted. As to the retaining of the lips of the corneal wound in apposition, the best splint which can be found is the one which nature supplies, the stiff cartilage of the upper lid. The most equable support for this natural splint, and one which never becomes irregular, regardless of the movements of the patient, is the tonic action of the orbicular palpebral muscle. When the lids are kept closed by a piece of adhesive plaster, this muscle affords a constant and uniform support to the incised eyeball. The

results of this new departure, in the treatment of cataract extractions, are very striking. The comfort to both patients and attendants is readily recognised. Patients can be dismissed from professional care in about half the time that any other mode of treatment will admit; and the percentage of successes will be fully up to that now secured by the most cautious ophthalmic surgeons with the old methods in use. This method of dressing eyes follows naturally upon the use of cocaine or the local anæsthetic. The vomiting, so common after the administration of chloroform or ether, would render such a dressing inadmissible. After a cataract extraction both eyes are closed by adhesive strips. In iridectomies only the eye operated upon is dressed, in this manner the other remaining uncovered and unprotected. These cases need no longer to be considered bad cases, but are truly peripatetics.

When the cataract patient is put to bed, no restrictions are put upon his movements. He may roll about at his pleasure, as there is no head band to draw irregularly on the wounded eye. He sits up to his meals, and gets out of bed for calls of nature. After the second day he may leave the bed if he prefers to do so. The moderate light in the room permits friends to read to and amuse the patient during the week's confinement. Usually the first dressing, applied immediately after the operation, is removed on the fifth day. The eyes can be examined then, when very little injection will be seen. The eye operated upon stands this moderate light without any exhibition of lacrymation or photophobia. Two or three days afterwards even sunlight can be admitted into the room for examination purposes without annoyance and without smoked glasses.

Notices of Books.

Micro-organisms and Diseases: an Introduction to the Study of Specific Micro-organisms. By E. KLEIN, M.D., F.R.S. Third Edition. London: Macmillan and Co. 1886.—No better example of the interest taken in the prevailing pathological pursuit of the present day—the search after specific micro-organisms—could be cited than the rapidity with which Dr. Klein's admirable little work has reached its third edition. As a compendium of knowledge upon the subject, and for the most part a faithful guide in the researches requisite to establish the presence and characters of bacteria, it holds an established position. Opening with chapters upon the methods of examination and cultivation, the bulk of the volume is occupied with concise but clear and sufficiently detailed descriptions of the various forms, aided by a plenitude of engravings, which are nearly all from original drawings. The discussion of the relation of septic to pathogenic organisms, including a confutation of Buchner's views, and such subjects as vaccination and antiseptics, are reserved for the closing chapters, so that the author has succeeded within comparatively small compass in giving as full a survey of the subject as could be desired. Invaluable to the student, it is a book which deserves to be read by all who follow with interest the directions in which modern research is leading in the attempt to solve the great problems of etiology.

A Manual of Microscopical Technology. By Dr. CARL FRIEDLANDER. Translated from the Second Edition by STEPHEN YATES HOWELL, M.A., M.D. New York and London: G. P. Putnam's Sons. 1885.—This little work has met with so much approval at the hands of its author's compatriots that we are not surprised at an appearance of an English translation, which will, we imagine, be equally acceptable to histologists in this country and America. It is a thoroughly practical and reliable book, not by any means overburdened with detail, but conveying sufficiently precise instructions upon all the "modern methods" of staining and preparation which may be required in histological and pathological investigation. Although we cannot altogether congratulate the translator upon his share of the work, yet he has erred on the right side, and succeeded in presenting a very literal translation of the original. As to the subject matter of the book, the directions given for bacterial investigation are especially worthy of note, and we may commend to all would-be discoverers the wise remarks upon the necessity of comparing normal with morbid tissues before declaring their opinion as to the nature or extent of the latter, for there is no department more open to erroneous interpretation or responsible for more hasty and ill-considered speculation than that of microscopical research.

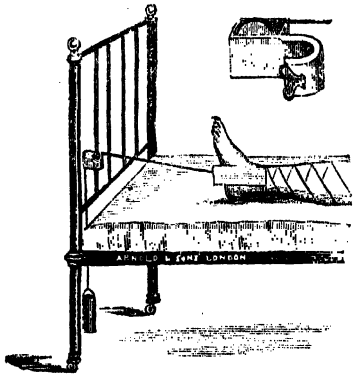
Sore-throat; its Nature, Varieties, and Treatment. By PROSSER JAMES, M.D. Fifth Edition. London: J. & A. Churchill. 1886.—The scope of this book is not sufficiently indicated in its title, for it embraces not only the inflammatory lesions of the pharynx and larynx, but other affections as well, including those of the trachea and bronchi, the thyroid and thymus, although it must be allowed that these last-named subjects receive but a minimum of description. The book, which has reached the dignity of a fifth edition, is written in plain language, and is thoroughly practical. It is therefore very suitable for the practitioner, who would hardly be able to devote the time requisite for the study of a more profound or elaborate treatise.

Traité Élémentaire d'Anatomie Médicale du Système Nerveux. Par CH. FÉRÉ. Paris: A. Delahaye et Lecrosnier. 1886.—No French neurologist is more fitted to write a medical anatomy of the nervous system than the author of this volume. The first section of the work is concerned with the central nervous system. The text does not merely describe the parts, but shows how they are altered by disease, and gives a general account of the pathology of the affections of the structure under discussion. This method relieves the usual monotony of mere descriptive anatomy, and effectually interests the reader. There are many illustrations of abnormal as well as normal structures.

The Asclepiad, No. 11, Vol. III.—The article on Alcoholic Asthenia is a very readable one, in the author's best vein, and showing strongly his excellent prejudices. The Skeleton in the National Cupboard is one more of those earnest appeals not to forget the foundations on which national existence and prosperity depend. Richard Wiseman and the Surgery of the Commonwealth (with portrait) is a most instructive biography. A very suggestive article is that entitled "Vis Medicatrix Naturæ," in which strong arguments are advanced against the favourite notion of the beneficence of Nature in restoring to health and harmonious working parts or organs in the physical economy which have become deranged by injury or disease. The section of Contemporary Practice and Literature shows a keen eye for the best. The popularity of Dr. Richardson's quarterly is now established beyond dispute.

Hospital Reports.

The Surgical Registrar of *University College Hospital* is again to be congratulated on the early appearance of his annual report of the surgical cases that have been under treatment during the year 1885. The completeness of these reports must be a source of gratification and of considerable utility to the members of the staff. The preface that Mr. Bilton Pollard writes to his report is remarkable, among other things, for its modesty. The labour to which the registrar has been put to produce such a report might well have found some mention in the preface, which is the customary repository of regrets at imperfections in the body of the work. All that Mr. Pollard says is: "The report for 1885 is similar in its general arrangement to that of 1884."



The fourteenth volume of the *St. Thomas's Hospital Reports* contains a large number of original articles by

members of the staff. Dr. Bristowe relates some interesting cases of Tubercle of the Cerebellum; Mr. Ballance, a case of Spasmodic Wry-neck treated by excision of a portion of the spinal accessory nerve; Mr. Clutton has an interesting paper on late Rickets; Dr. Hadden calls attention to some of the usually less conspicuous features of Chorea; Dr. Gulliver describes a case of Gangrene of the Lung consecutive to acute pneumonia; Mr. Shattock gives a notice of the more interesting additions made to the museum during the year. The medical report is signed by Dr. Hadden and the surgical by Mr. Battle.

New Inventions.

EXTENSION PULLEY.

THE accompanying illustration depicts an extension pulley which I have had made, and which is used at the Cork Children's Hospital, to the exclusion of nearly all the old extension arrangements. By means of the side screw

it is easily attachable to any ordinary bedstead, and can be raised or lowered at pleasure, so that a pull can be had from any direction. Messrs. Arnold and Sons, West Smithfield, have arranged to manufacture these pulleys.

NICHOLAS GRATTAN, F.R.C.S.E.,
Senior Surgeon, Cork Hospital for Women and Children.

THE TRAVELLING AND NURSERY CONVENIENCE.

THIS is undoubtedly a very useful contrivance, and will be welcomed by mothers and nurses when travelling with young children. Its chief recommendations appear to be—its great portability; the neatness of the case, effectually disguising the purpose for which it is intended; and the security with which the contents of the pan may be enclosed, being hermetically sealed by closure of the lid, which is provided with an elastic waterproof pad. The apparatus may be readily taken to pieces, to facilitate cleansing, and its cost is very moderate. The patentees are James Allen and Sons, 21 Marylebone-lane, W.

GUY'S HOSPITAL.—An excellent portrait of the late Dr. Alfred Swaine Taylor, F.R.S., the distinguished medical jurist, toxicologist and chemist, has been presented to Guy's Hospital by his son-in-law, Mr. F. Methold, with a request that it may be hung in the theatre in which the professor lectured for so many years.

UNIVERSITY COLLEGE, LONDON. — Sir William Roberts, M.D., F.R.S., Professor of Clinical Medicine in the Victoria University, Fellow of University College, has consented to preside at the annual dinner of the Faculty of Medicine, which will take place at the Freemasons' Tavern on Monday, October 4th. Tickets may be had of the Honorary Secretaries, Dr. Poore (30, Wimpole-street) and Mr. Stonham, F.R.C.S. (109, Gower-street).

ACTION AGAINST A LIVERPOOL DOCTOR.

CASEY *v.* IMLACH.

AT the Liverpool Assizes on the 6th inst., before MR. Justice Cave and a special jury, an action was heard in which John Casey, a labourer, and his wife Mary were the plaintiffs, and Francis Imlach, M.D., one of the senior surgeons of the Hospital for Women, Shaw-street, Liverpool, was the defendant. The action was brought to recover damages from the defendant for performing improperly an operation upon the female plaintiff without her consent. The defendant in his pleadings denied the allegations made against him. Mr. French, Q.C., with him Mr. Walton, appeared for the plaintiffs, the defendant being represented by Mr. Bigham, Q.C., and Mr. W. H. Butler.

Mr. FRENCH, in opening the case, explained that the male plaintiff was formerly a sailor, but that he now worked on shore for Messrs. Singlehurst and Co., the owners of the Redcross line of steamers. The female plaintiff was married to him in 1874, and her complaint against the defendant was that he removed both her ovaries without her consent, without informing her what the result upon her after-life would be, and without there being any necessity for such an operation. By this operation he took away from her, at the age of thirty-nine years, a material portion of her genital organs, and left her incapable of conceiving. The operation was one not long known in surgery, and one which so seriously affected a woman that it was not had recourse to by surgeons except under circumstances of the gravest necessity in certain classes of disease for the purpose of saving human life. In the case of Mrs. Casey it was not an operation which any surgeon should have had recourse to, and if it had been, the fullest information should have been given to her of what her future life would be, so that herself, her husband, and her friends might form their own judgment as to whether the operation should be submitted to, or whether the woman would be prepared to run any risk there might be in continuing under medical treatment, and trust to that alone for restoration to health. Not one word was said to her as to the nature of the operation—that she was to be unsexed—no suggestion to her that the operation was so serious that her friends should be consulted, no intimation that the disease was one which, under medical treatment, with care, rest, and constant attention, could be dealt with, but an intimation that, under the penalty of being a dead woman within six months, the operation should be at once performed. As a result of the operation her bodily system was entirely altered, but the pains from which she had previously suffered disappeared. Her health and her bodily comfort were, however, in no degree improved; other pains of an equally serious character came on, and her health became worse than ever it was before. One painful circumstance in connexion with the case was that, according to his instructions, what medical men would expect to follow from an operation of this kind had actually occurred, and the result had been a change not only in her own life, but in the life of her husband. Under these circumstances the plaintiff claimed that she was entitled to be informed by the defendant not alone of the danger of the operation he was about to perform, but above all in her case, as a married woman, she was entitled to know what the after-effects would be upon her own life and the life of her husband. Dr. Imlach, a surgeon not of very long standing, had become very skilful in his profession. He had had great experience in surgical cases, and had performed this novel operation very frequently. The operation was one which had had not more than from twelve to fifteen years' existence in this country, and among the body of surgeons there was not any large number who practised it; but among those who did practise it there was, as he understood, a well-recognised rule that, looking to the gravity of the results as well as to the danger itself, it should not be had recourse to except in very grave cases. The complaint from which Mrs. Casey was suffering at the time, according even to the views of surgeons who strongly supported this novel invention in surgery, was not one in which the operation should be had recourse to. The defendant, as surgeon, made the usual entry in his note-book at the time of the operation, and described it as being for hæmatocele and hæmatosalpinx.

Mrs. CASEY, the plaintiff, was then called. She stated that in March, 1881, she first experienced some illness, from which she suffered afterwards, and she attended the dispensary of the Ladies' Charity and Lying-in Hospital in Myrtle-street, Liverpool, as an out-door patient. From April, 1881, to March, 1883, she was quite free from these pains. In April, 1883, she had another attack of the same pains, and she saw Dr. Utting, who told her she was suffering from inflammation of the bowels. He prescribed for her, and she became much better. She, in June, 1883, went to the Women's Hospital in Shaw-street and saw the defendant, who gave her medicine, which she took until August; and then she was well until the beginning of December, 1884, when she felt a similar pain in her abdomen, which continued for about half an hour. She went to the defendant on Dec. 8th and told him about this, and he then examined her. He told her she would have to undergo an operation, as she was suffering from inflammation outside the womb. On Dec. 15th she entered the hospital, and was operated upon on the 18th. She was never examined or seen by any other doctor, and was not told by him or anyone in the hospital what the result of the operation would be. On Dec. 31st she was taken home in a cab, and ten weeks afterwards she went to the defendant and complained of weakness. She also told him she had not been "unwell" (meaning that ther had been no menstrual discharges), and the defendant replied, "No, you never will be; you have been 'unwell' too much;" and explained that the diseased parts he had removed were the cause of this. On Jan. 29th last she went to him to complain about the operation, having found out that he had removed her ovaries. She considered her health to have been worse since the operation than it was before, and between herself and her husband it had made a wonderful change. She had since been under Dr. Wallace of the Royal Infirmary.

Cross-examined by Mr. BIGHAM: She had been a hard-working woman until attacked by pains in the lower part of the abdomen, and had had five children—four of whom had died in childbirth and the other, born on Oct. 7th, 1878, was now alive. In 1879 she suffered from pains which she thought were not connected with her womb, but with her stomach, and she consulted Dr. Wilson at the Myrtle-street Hospital, who gave her some medicine which removed the pains. About March, 1881, she had a recurrence of pains in the lower portion of the abdomen when four months in pregnancy. She remained in good health until April, 1883, when she was treated by Dr. Utting's assistant for inflammation of the bowels. In May she began to become "unwell" too often. The menstrual discharge was about the usual quantity, and was accompanied by pain. In consequence of this she, in June, went to the hospital again, and was prescribed for by some medical man whom she believed was Dr. Davis. She then saw Dr. Imlach and remained under him from June to August, when the pain from which she occasionally suffered ceased. On Dec. 7th, 1884, the pains returned, though they were not so bad as previously. She went to Dr. Imlach at the hospital, which by this time had been removed to Shaw-street, who examined her on December 8th. She did not tell Dr. Imlach in 1883 that she was suffering from constant pain, or from frequent and unusual bleeding. She never told him she had had a flooding of three weeks, or that she had been to many doctors to get cured. He did not tell her on December 8th, when he examined her about the private parts, that she was suffering from some disease in that region. She understood him that she was suffering from internal inflammation. Dr. Imlach never mentioned the word ovaries, and she did not at that time know what they were. He did not tell her that the inflamed parts were connected with childbearing. She did not hear that her womb was displaced, but she understood that by the operation Dr. Imlach would bring down the womb and destroy the cause of inflammation.

Mr. BIGHAM: Did you form that opinion from anything he said, or was it your own opinion?—It was my own opinion.

Was Dr. Imlach kind to you before the operation?—Yes.

Kind and considerate?—I don't know; he was not very considerate when he took my ovaries away. (Laughter.) The nature of the operation was never discussed between me and the lady superintendent of the hospital or the nurses.

Did you, a married woman, know at that time what it meant if you were never to be "unwell" again?—I only knew that I could never have any more children.

Were you not told, amongst other things, that you never would be unwell again?—Never.

But if you had been told that, you would have known it meant never to have any more children?—If I had been told that, I should never have submitted to the operation.

Witness, continuing, said that when she was told by Dr. Imlach in March that with the operation she would never be "unwell" again, that was the first time she ever heard of such a thing. She first became acquainted with the fact that her ovaries had been removed in December last. She had told Dr. Imlach that she would have the law of him, but she did not tell him that she knew an attorney, and an individual would pay the expense. She had heard that Dr. Wallace was very eminent, and that was the reason she went to see him; but she did not hear that Dr. Wallace was taking a considerable part in the medical discussion regarding Dr. Imlach's operations.

JOHN CASEY, the husband of the previous witness, was called to state that he never heard of the serious operation to be performed on his wife, or he would never have consented to it.

The examination of JOHN WALLACE, M.D. Edin, and Professor of Midwifery at the Liverpool University College, was then read, he being too ill to attend. He stated that he had examined the plaintiff and read the note-books of Dr. Imlach, and she had explained her symptoms before operation to him. From what he knew of the case, such an operation as the removal of the ovaries ought not to be performed. He would not perform excision of the ovaries except in very extreme cases, and after very long observation. Assuming that the plaintiff saw the defendant from time to time, from May to August, 1883, and then not until Dec. 8th, 1884, and was only in hospital from Dec. 15th to the 18th, that was not, in his judgment, sufficient opportunity for observation to justify the operation. He should consider that the disease would be amenable to rest and medical treatment. Sterility followed the excision of the ovaries, and loss of sexual feeling, which might be kept up for a year, but after that declined. Hæmatocele and hæmatosalpinx did not produce sterility. The patient might be temporarily sterile while it lasted. In any such an operation as the removal of the ovaries the operation ought not to have been performed without explaining to the patient its nature. It was a well-known fact that it produced a masculine appearance; in an older woman the appearance was not so marked, but it made a young woman old before her time.

In cross-examination Dr. Wallace had stated that he should perform the operation of abdominal section only when continual hæmorrhage threatened life, with the object of tying the bleeding parts. He would perform excision of the ovaries when they were enlarged from cystic disease, for fibroid tumours of the ovary, or early cancer. Different men had different views as to when the operation was necessary. If there were salpingitis adhesions to the Fallopian tubes and ovaries, that would not justify the operation. If the patient had any pain or inconvenience that would make a difference, and it would then depend upon the time of life.

CHARLES STEEL, surgeon at the Women's Hospital in Shaw-street, was then called, and before he was sworn stated that he knew nothing of this particular case.

His LORDSHIP: That is not very material; we have a number of witnesses of that sort.

Mr. FRENCH: You mean you attend here on subpœna?—Yes.

Mr. STEEL was then sworn, and he stated that from Dr. Imlach's entry in his note-book that Mrs. Casey was suffering from hæmatocele and hæmatosalpinx, he did not think there would be sufficient disease to justify the excision of the ovaries. As to sexual desire, he could only speak within twelve months, as he had not made any other inquiry. Of the patients who have been operated upon in about twelve months, some say the feeling has not gone, others that it has.

In your acquaintance with hospital management, can you tell me whether in operations of this gravity there is not a custom as to the attendance of the senior medical officers—is it usual for the operating surgeon to have the benefit of the advice of the senior medical officers?—That is usually done.

Can you tell us in this case of Mrs. Casey whether there was any consultation between Dr. Imlach and any of the senior medical officers?—I did not receive notice; so that to my knowledge there was not.

In the case of hæmatocele, what would be the proper course of treatment in order to extract the blood?—As far as length of time is concerned, I should have the patient under my care some time before I operated, in order to try rest and medical attendance.

Had Dr. Imlach, in your judgment, sufficient time to watch the case, to try medical treatment, and to justify the operation?—I should take rather a longer time myself, but I cannot say as to this case.

Do you consider in this case there were sufficient grounds to justify the operation?—Not having seen the patient, I really cannot answer.

With the information now before you, and Dr. Imlach's note-book, what do you say?—Well, if I am to judge merely by that, I should not operate myself in such a case.

Before operating in a case of this kind what information, in your judgment, ought to be given to the patient as to the nature of the operation, and the subsequent effects of the operation upon herself?

Mr. BIGHAM: I submit that is a question for the jury.

Mr. FRENCH: I am quite content it should be so.

Cross-examined by Mr. BIGHAM: Whether you would perform an operation or not would depend upon an examination of the patient?—Yes. I have five times performed this operation of excision of the ovaries, and once made an exploratory operation, in which I performed the abdominal section, and did not remove the ovaries.

If you ascertained that the ovaries were sclerotic, and that the patient was suffering from salpingitis and intense pain, would you then think it was a proper case for operation?—I should not operate then under the circumstances.

But if the ovaries are sclerotic the woman, I suppose, is past childbearing?—Not exactly. It is very difficult to say. Very little is known about sclerotic ovaries.

If it had been ascertained that the ovaries had fallen down into Douglas's pouch, and that the uterus was displaced, would these two facts dispose you, in addition to the others, to think that the operation was a needful one?—That is the condition I found them in when I replaced them.

Do you think that it would be a proper thing, in a case of definite evidence of all these symptoms which had resisted known methods of treatment, to remove the ovaries?—I should be guided very much by the position of the case.

Re-examined by Mr. FRENCH: Is it not a matter of very great difficulty to diagnose whether the ovaries are sclerotic?—I should say very difficult.

The Court then adjourned until Saturday.

On Saturday morning, JAMES MOORE BENNETT, M.D. and surgeon, said he had been twenty-five years practising in Liverpool, to a considerable extent in connexion with diseases of women. He had had his attention called to the operation performed by Dr. Imlach, and he did not see anything that would render it necessary, without first using other means of treatment. In his opinion the defendant had not given sufficient time for medical treatment before having recourse to such an operation.

Mr. FRENCH: Are you able to say from your own experience in the profession whether diseases of this character are amenable to medical treatment?—They have been. I have treated a large number myself without having recourse to surgery.

How is the female affected by this operation?—It destroys the power of procreation, stops the menstrual discharge, and it is believed by a large number to leave the female unsexed.

Then I may take it, shortly, the effect is the same as the castration of a man?—Yes.

Is that answer based partly upon your scientific knowledge of the human body and partly upon inquiries and information you have had in the course of your practice from women themselves?—It is.

In your judgment, would the giving of information by an operator of the nature and consequence of an operation of this kind be likely to be injurious to the patient, or to render the operation more dangerous or difficult to the patient?—It would make her nervous.

His LORDSHIP: People have a right to know the nature of an operation, no matter what the immediate consequence may be.

Mr. FRENCH: You have heard that in Dr. Imlach's answers to interrogatories he says that in 1883 she complained of severe pelvic pain, irregular flooding, and so on. Does that change the judgment you have expressed in reference to this operation?—Somewhat.

In what does it show that the case was more difficult from his answer to his description in the note-book?—It shows the frequent pain and the continued hæmorrhage.

But even assuming this, what do you say as the time necessary for observation before operation?—I think the patient ought to have been longer under observation.

Cross-examined by Mr. BIGHAM: Assuming the symptoms to be such as my friend has just read to you, and they had been under observation for a considerable time, you don't think the operation would have been an unwise one?—Not for a considerable time.

What time do you consider sufficient?—I have seen some of these cases under observation for years. I should think Dr. Imlach had not sufficient time for observation, but a great deal would depend upon the result of a personal examination of the patient and upon the opinion a medical man would form after it. This operation is seldom necessary except in cases of tumour.

Do you think there are ever cases of sclerotic ovaries and salpingitis where this operation is necessary?—It is quite possible.

Would any information convey to another man the knowledge the doctor gets from an examination?—None.

Is it true that cases of sclerotic ovaries are peculiarly resistant to palliative remedies?—It has so been said.

And that is the opinion of many medical men?—Yes.

In a case of persistent salpingitis, is it true that with rest a patient may get well?—Yes.

Is it true that when the ends of the tubes are blocked removal is the only form of giving relief?—Not always; the blood may be absorbed. I have seen in the answers that a clot of blood was discovered in this case.

Is it a moot question amongst doctors as to whether this operation destroys sexual desire or not?—Yes.

Re-examined by Mr. FRENCH: Rule 39 of the hospital regulations provides that "No operation of a dangerous character shall be performed in the hospital without consultation between one of the medical officers for in-patients and one of the consulting medical officers and the operators." Is that in your judgment a prudent rule for a surgeon to follow?—Certainly.

Have you in your experience had cases with symptoms even more serious than this, upon Dr. Imlach's statement, which have yielded to medical treatment?—I have.

His LORDSHIP: Have you read anything in the note-books, in the answers to interrogatories, to make you think this operation on this woman was a proper one?—Nothing that would cause me to operate in a similar case.

In your judgment would delaying the operation have been injurious to the patient?—I should think not.

THOMAS FREDERICK GRIMSDALE, physician and surgeon, practising in Liverpool for the past thirty-nine years, said he attended upon his subpœna, and had not given proofs to either side. For many years his practice had been in connexion with female patients, and he was senior physician to the Women's Hospital in Shaw-street. During last year there were 111 operations of the kind in question performed, and in the previous year forty-four. Whilst he had the strongest possible objection to giving evidence on an abstract or supposititious case, he could say that the excision of both ovaries from a patient when, according to the defendant's note-book, she was suffering from hæmatocele and hæmatosalpinx, and her highest temperature was 100° and her lowest 97°, did not commend itself to his judgment.

Mr. FRENCH: Assuming treatment in 1881, recovery, good health until 1883, treatment in June and July, then health until December, 1884, one attendance on Dec. 8th, hospital on the 15th, operation on the 18th: in your judgment, was there a sufficient medical treatment or duration of time before having recourse to surgery?—If it was a case of hæmatocele, I should say it could not have been the same attack. They must have been distinct attacks.

Therefore, I may ask you, in December, 1884, ought there to have been a further considerable period of waiting and medical watching before having recourse to surgery?—Well, I draw the line at hæmatocele entirely.

You would not have it all?—Certainly not, from my experience. Hæmatocele and hæmatosalpinx combined would require a long medical watching before having recourse to surgery, and I should not have had recourse to surgery unless there was extra-uterine fœtus.

Assuming hæmatocele and hæmatosalpinx to exist, would you rely upon medical treatment, or have recourse to the knife?—I have had a great many cases in my life, and never had an idea of resorting to the knife. Of course, the

great majority were before this treatment was known, and a very great majority have got well under medical treatment alone. The operation does not commend itself to me at all. From the very great success that I have experienced, together with other medical men, the patient will recover from simple treatment, especially from prolonged rest. As far as I know, the operation has been less successful than the milder treatment of medical attention and rest. According to the last annual report the mortality in this hospital was about 33 per cent.

What judgment have you formed as to how women are affected by this operation as to sexual desire?—I have made some inquiries, and the result is that it varies very considerably. Probably in about half the cases there is no change whatever. In some the desire is impaired slightly; in others it is taken away altogether.

In your own practice, have you ever found it necessary to have recourse to this operation?—I have suggested it, but not in many cases.

Cross-examined by Dr. BIGHAM: Have you been present at any operations performed by Dr. Imlach?—A few.

You have heard the cross-examination of Dr. Bennett?—Yes.

Do you agree with him that in forming an opinion the most important thing is a personal examination of the patient?—Certainly. I think that a man gets a personal idea of the case by examination which he cannot communicate to another, and that is the reason why I object to give these *ex parte* statements without seeing the patient. I should doubt it to be possible that an experienced man could detect sclerotic ovaries by examination. I am now invited to these operations, but for about eighteen months I was not invited at all. I have been medical officer of the institution since it was opened two and a half or three years ago. There has been a good deal of discussion and difference of opinion about the necessity of these operations throughout the whole profession.

His LORDSHIP: We cannot have that opinion produced here. We must go by evidence.

Witness (continuing): I do not recognise the present operation at all. I was not invited until the beginning of this year.

Mr. BIGHAM: Do I understand you would recognise this operation of abdominal section and removal of the uterine appendages in any case?—Yes, in myoma, and if there be symptoms of pus in the tubes.

Dr. Imlach, in his answers to interrogatories, says that when the plaintiff first consulted him in 1883 she complained of severe and constant pelvic pain from which she had suffered for about five years, also frequent, prolonged, and exhausting hæmorrhage from the womb. When she was examined per vaginam, the womb was found to be retroverted, fixed to the sacrum, and very painful to the touch. The ovaries and Fallopian tubes were pressed down into Douglas's pouch; the ovaries seemed atrophied, and the Fallopian tubes could be felt to be thickened. Can you say whether the conditions there described are sufficient to justify the operation?—If they were just as there described, the operation would not have occurred to me.

Mr. ALEXANDER, late surgeon to the Brownlow-hill Workhouse Hospital, Liverpool, was called, to say that he had made over 3000 post-mortem examinations, and in only one female had he found hæmatocele.

Dr. BURTON, one of the medical men at the Women's Hospital, was called, but did not appear.

This closed the plaintiff's case.

Mr. BIGHAM, having briefly opened the case for the defence, called

FRANCIS IMLACH, the defendant, who said he was M.D. Edin., M.R.C.S., and one of the honorary acting medical officers for the Women's Hospital in Shaw-street, Liverpool. He graduated in February, 1872, and had both before that time and since devoted particular attention to diseases of women. He did not remember seeing Mary Casey before May, 1883, when the hospital was in Myrtle-street, and his note of that visit was "menorrhagia—three weeks." His impression was possibly there was a miscarriage; but this she denied, and he never found out anything to suppose that it was a miscarriage. Her complaint was as to this frequent hæmorrhage, which would come on almost at any time. She complained of a pain in the left side of the stomach low down, and he recommended her rest and good food. On Dec. 8th, 1884, she called at the institution in Shaw-street, and he examined her abdomen. There was some indefinite dulness where there should have been resonance; but it was not distinctly felt. It had no definite limitations in the pelvis. He examined her per vaginam, and the first thing he found was that the uterus was dragged out of place, down to the left, and was immovable. His fingers could feel the posterior portion of the uterus and the vaginal viscera. The plaintiff was a spare woman and a very good subject for examination. At that time he formed an opinion that the position of the uterus was due to contraction from previous inflammation of the left broad ligament, and partly due to adhesions of the uterus to the pelvic walls. When he operated he found this opinion wrong, for he found that adhesions of the tubes were the cause, and not contraction of the broad ligament. At this examination of Dec. 8th he could feel with his fingers into the space behind the uterus—Douglas's space. He could feel the Fallopian tubes behind and below the uterus, as if they were two solid limbs like two little fingers. There was a membrane between them and his fingers, but he could feel that they were thick. They were certainly not in a healthy state, from the fact that he could feel them in that place and in that condition. It was quite a difficult matter to diagnose sclerotic ovaries before operation. He could feel two little substances which from their relation to the tubes he was convinced were the ovaries. By pressing down the abdomen with one hand and working the fingers of the other, he could get to them, and he found they were hard and small. He wrote down at the subsequent examination that they were atrophied ovaries, but at this examination he wrote salpingitis, because he was surer of that than the sclerotic ovaries. There was no doubt about that. The womb was painful to the touch, and there was great tenderness. She told him she had been to any number of doctors since 1879. What impressed him very much was that she had told him she had been treated by a general practitioner for inflammation of the bowels, which made him rather suppose it might turn out to be, on examination, inflammation of the tubes and ovaries, which gave symptoms much like those arising from inflammation of the bowels. His examination indicated a serious state of the woman's health. It seemed to him there was great danger of her losing her life through the irregular loss of blood, and that nothing short of an operation was required. He told her the nature of the operation, that she would never have any more children after it, and that he was fully convinced she was then sterile. On Dec. 15th she entered the hospital, and on the 17th he again examined her, when the appearances were similar to those of ten days previously. In his abdominal note-book he made the entry: "Irregular menstruation for last five years; pain in the left hypogastrium, worse just after cessation of menstruation; habits doubtful, probably irregular; weak and miserable from constant pelvic pain and hæmorrhage. Condition of the uterus—dragged to the left by contraction of the broad ligament, also retroverted slightly; mobility restricted; length of cavity normal; ovaries atrophied." Before performing the operation, he had a consultation about her case with Dr. Lupton, one of the acting medical officers, who was suffering from spinal paralysis, and too ill to give an account of the matter. Present at the operation were the lady superintendent of the hospital, at least one nurse, and Dr. Davies, one of the acting medical officers. When he made an incision of the peritoneal cavity it was purple, showing that there was blood inside, and that he was right when he judged there was peritoneal hæmatocele. He opened up the peritoneum, put his fingers in, and drew out a blood clot that was free in the pelvic cavity. It was not one clot, but was composed of two or three, and was about the size of a small orange. He felt the uterus drawn down on the left side, and therefore turned up on the right. The ovaries were low down in Douglas's space, but he easily drew them up separately, and when he drew them out of the incision with his finger he found that he had also brought up the appendix vermiformis. It was not usual to find this appendix adhering to the fimbriated extremity of the right tube. The outer half of the right tube contained an old blood clot which, according to his recollection, was about the size of a cork, and was sticking out of the fimbriated extremity. At first he thought this clot was fæcal matter from the intestine; but, looking at it more carefully, it seemed to him to be a blood-clot ulcerating into the appendix vermiformis. He separated the right tube from the appendix, and care-

fully looked to see whether there was any perforation, and satisfied himself that there was. The right tube was thickened from chronic salpingitis, and there was also a dense blood-clot. The inflammation was so severe that it bled. Then he removed the ovary on that side. It was low down, very small, contracted, and hard, and he removed it, along with the tube that was thickened and inflamed. He felt for the left tube, and found that it was pulling the uterus down. It was thickened and dense and adhering to the pelvic walls. After separating the adhesions he drew it up to the surface outside the incision and found it a source of great danger to the woman. He removed it with the ovary. From what he saw of the ovaries he became certain they were sclerosed throughout. They were contracted like the hard kernel of a hazel nut. He was certain it was a case of hopeless sterility; it was the last stage of inflammation. The presence of the tubes was dangerous to the woman's life if left as they were. He had no reason to suppose that sclerotic ovaries were dangerous to life, but if they had been healthy and the tubes as he had described, there would have been no advantage in leaving the ovaries. Before he removed the ovaries he had formed an opinion that the operation was a proper one. In March following the plaintiff came to him, and he found menstruation had ceased and there was nothing abnormal.

Cross-examined by Mr. FRENCH: Did you consult anyone beside Dr. Lupton about this case?—No.

Did Dr. Lupton see the patient?—I cannot recollect, but my distinct impression is that he did not.

Don't you know that by a large body of practitioners this operation is looked upon with great disfavour, and don't you think it would have been better to get the advice of another doctor before operating?—Dr. Lupton had seen several cases like this before, and he agreed with me. He is perfectly familiar with my methods and with my accounts of the cases. My recollection is that he was to see the patient, but we had had a very heavy operation, and I was so exhausted, as the operator that we simply talked this case over.

Was this case so serious that it could not stand over for a few days to allow you to recover and consult with another medical officer?—I think the question of hæmorrhage made the matter an urgent one.

Urgent to one or two days?—No; I don't suggest that.

During the year 1885, how many castrating operations were performed in this Women's Hospital?—I don't think the term castrating is proper.

Then in how many cases were the uterine appendages removed?—I should say that a hundred was near the mark.

And in 1884, how many cases?—I think thirty or forty.

In how many cases during the last two years have you yourself operated for the removal of uterine appendages?—In many I removed both, but if I include where there was only one, nearly 135 cases. This includes my private as well as hospital practice.

In your practice at this hospital have you habitually had recourse to this operation for hæmatocele?—I have always operated in cases of intra-peritoneal hæmatocele where the symptoms have convinced me it was dangerous to life.

Did you tell Mrs. Casey to tell her husband of the nature and results of this operation?—I can't swear to any distinct conversation in which I should tell her to go home and acquaint her husband, but I have no doubt I should do. I can't remember on Dec. 15th, when she came back, inquiring whether she had consulted her husband or any of her friends, but should assume consent because she had been at home for a week.

Can you remember anything said by you to indicate that there was a risk of her losing the capacity for sexual desire by this operation?—I would not say that because it is contrary to my experience. I never met a case in which there was loss of desire. There is no relation between the sexual feeling and the ovaries that I have been able to discover. I advised the operation, and told her it was a removal of the parts that were diseased, which parts they were, and the consequences that would follow.

Have you made any attempt to have Dr. Lupton examined in this case with regard to your speaking to him about this examination?—No, I have not.

Did you know what Dr. Grimsdale's views with regard to the unwisdom of performing this operation were?—I don't think his views were definitely formed at that date.

Did you abstain from calling in Dr. Burton as a consultant because he was against performing the operation?—He is performing the same operation himself.

Cross-examined by Mr. BIGHAM: You have been told that the medical profession complained because you did not call in any other doctors in consultation. Did that relate to your practice at the hospital, or generally?—My practice at the hospital.

Have you been to see Dr. Lupton?—I have seen him often.

Have you tried to have a conversation with him on this subject?—No; but I have had conversations frequently with him to get him to recollect cases of consultation he had with him in 1885, and he has always shown he could not recollect, and he could not speak of medical matters.

Are there two kinds of hæmatocele—intra-peritoneal and extra-peritoneal?—Yes.

And this was intra-peritoneal—the most dangerous form of hæmatocele?—Yes.

LAWSON TAIT, F.R.C.S., and surgeon to the Birmingham Hospital for Women, said he performed the first operation for the removal of uterine appendages on Feb. 11th, 1872, and, including abdominal sections, he had operated about 1600 times. Intra-peritoneal hæmatocele was very distinct from extra-peritoneal and was fatal in 96 per cent. of the cases if left long. In the great majority of cases it was fatal in three hours, and the longest time he had known before it was fatal in one attack was forty-eight hours. He had heard the evidence of Dr. Imlach, and from his description of the case he could say that the operation was a most proper one.

Mr. BIGHAM.—You have heard his diagnosis before the operation, what does that indicate as to the sterility of the patient?—There can be no doubt that the woman was completely sterile before the operation. His account of the operation itself confirms the diagnosis.

From your experience what effect has this operation upon the sexual desire?—In no case that I have ever asked the question have I found it destroy the sexual appetite at all, and in very many cases where the disease destroyed it the operation has restored it. Chronic salpingitis with adhesions apart from or connected with hæmatocele would be a proper case for operation if the symptoms were severe enough. From the plaintiff's own description of the symptoms, I should say that is a case of recurring intra-peritoneal hæmatocele. She described the case exactly.

His LORDSHIP: You say the longest period before death you have known has been forty-eight hours; but here you have a woman who has three previous attacks, none of them fatal? I know of no case like this; it is unique.

Mr. BIGHAM.—From the diagnosis you have heard of Dec. 8th and 17th, would there have been any danger in leaving the case longer?—I say Yes; because the amount of blood found at the time of the operation was very considerable, and if the bleeding had been going on the patient would certainly have died. It most certainly was an urgent case according to the amount of blood.

His LORDSHIP: In the case of intra-peritoneal effusion how is the blood got rid of?—A great majority die of the hæmorrhage.

Cross-examined by Mr. FRENCH.—Before this action was brought was there a discussion amongst medical men on this question in which you took part? Was there a printed discussion between you and Liverpool doctors with regard to Dr. Imlach and his system of treatment at this hospital in Shaw-street?—There were several letters published in medical journals.

There is a letter of yours in the *Medical Press* of March 3rd, and I will read to you a passage: "I assumed, of course, in my previous discussion of this matter in your columns that Dr. Imlach was actuated by principles similar to those which I myself had adopted. I am not yet prepared to say he is actuated by others, but I am bound to say that after reading the discussion in your columns to-day, and still more after reading the paper by Dr. Imlach himself in the *British Medical Journal* of last Saturday, I think he has departed from those principles. He certainly has gone a great deal further than I think can be justified in the removal of appendages for hæmatocele; but I want to guard against condemning Dr. Imlach, because, after all, it may be proved that he is on the right side of the question. At present I do not think so." Can you now point out anything in the course of this case to make you change the opinion you expressed in this letter?—The opinion expressed there is very simply explained. It arose from a want of precision in Dr. Imlach's description of the two kinds of hæmatocele, and I assumed,

perhaps too hastily, that he removed the appendages for extra-peritoneal hæmatocele. I afterwards found that this assumption was not correct. In intra-peritoneal hæmatocele surgical operation is absolutely demanded, and immediately.

Can you explain why Dr. Grimsdale has not had occasion to remove the ovaries?—I can point to a large number of cases which have passed through Dr. Grimsdale's hands, which have come to me for operation, and the explanation is that he has not followed the advances made so as to recognise the value of the operation.

On December 8th, if there had been a diagnosis of intra-peritoneal hæmatocele, what decision would you have come to?—I should have operated upon the 8th or 9th.

Then that would have been really a case of urgency?—I should have regarded it as such.

Did you hear Dr. Imlach this morning say that even on the 18th there was no such urgency, but that he could wait a day, or even two or three?—That would depend upon the condition of the plaintiff, about which I can form no opinion.

Have you known medical treatment tried to save a patient's life for intra-peritoneal hæmatocele?—I have, and known it always to fail.

Do you assume, then, that in cases of hæmatocele successfully treated there was no intra-peritoneal hæmatocele?—I can make no such assumption; I can only speak of my own practice.

Mr. BIGHAM: Quite irrespective of hæmatocele, do you think from the description of the salpingitis and pain there was quite sufficient to justify the operation that was performed?—Yes.

JAMES AVELING, M.D., senior physician of the Chelsea Hospital for Women, gave evidence that from the descriptions given the operation was a proper one. The exploratory incision was warranted by the symptoms, and then, having regard to the discovery made afterwards, the removal of the uterine appendages was proper. There were two things which he thought justified the operation: one was the inflamed condition of the tubes, and the other the small and hardened ovaries. He believed the removal of the ovaries had no detrimental effects as regarded sexual desire. In the case of eunuchs the sexual desire was not removed.

Cross-examined by Mr. FRENCH: He did not attach much importance to what was called intra-peritoneal hæmatocele. He believed it existed in this case, but did not think it of so much importance as the other things he mentioned.

His LORDSHIP: Would you perform this operation where there was nothing more than a sclerotic condition of the ovaries?—I have done so; it makes life miserable.

If there is pain after an absence of eighteen months, is it necessary to cut out the ovaries?—Certainly not.

THOMAS SAVAGE, F.R.C.S., surgeon to the Birmingham Hospital for Women, deposed that the operation was a proper one under the circumstances, and that Dr. Imlach had plenty of opportunity of ascertaining the condition of the patient. In a large number of cases the operation did not interfere with sexual desire, and in others it increased it.

By His LORDSHIP: He was quite prepared to say that in this case recovery by medical treatment was impossible. Temporary recovery was not probable. Although nature had succeeded three times in effecting a recovery, he did not think it would have been the slightest use giving nature a chance again, as every time the pain occurred the woman was on the brink of a precipice.

JAMES GREIG SMITH, surgeon at the Bristol Royal Infirmary; Mr. Sinclair, physician for the diseases of women at the Southern Hospital, Manchester; Nicholas Kendrick Marsh, surgeon, Liverpool; James Muir Howie, M.B., Liverpool; Andrew Stewart, L.R.C.P. and L.R.C.S. Edin., Birkenhead, also stated that the operation was a proper and necessary one.

Dr. DAVIES, one of the honorary assistant medical officers at the hospital in Shaw-street, Liverpool, said he attended nearly all the operations at the hospital, and he gave ether to the patient in this case. He had no distinct recollection of the operation. He had not known a single case of the removal of uterine appendages which he disapproved of, and had never known of the removal of healthy ovaries except in the case of fibroid and solid tumours. From Dr. Imlach's description this was a case for surgical treatment; medicine would have been no use at all. It was a case for prompt operation, as she was liable to recurring [illegible] of hæmatocele, which was a danger to life.

[illegible] examined by Mr. [illegible]: Do you at this hos[illegible] distinction between intra- and extra-peritoneal hæmatocele?—I have not yet seen a case of extra-peritoneal hæmatocele.

Miss Carless, lady superintendent of the hospital, and Miss White, formerly nurse, deposed to telling the plaintiff what the result of the operation would be. Miss White stated that she told Mrs. Casey that she would never be "unwell" again, and the reply was "a good thing too," or words to that effect.

This closed the evidence for the defence, and his Lordship was about to adjourn until Monday, when the jury intimated that they had made up their minds about the case, and were ready with a verdict.

Counsel in the case agreed to accept the decision of the jury, who then returned a verdict for the defendant.

On the application of Mr. Bigham, his Lordship certified for a special jury.

SURGICAL CASES.

To the Editor of THE LANCET.

SIR,—Permit me to offer a few observations on some surgical cases published in your journal.

1. *Delayed union of lower jaw after division in Sédillot's operation.*—The writer of the editorial preface to my two cases of Sédillot's operation for the removal of the entire tongue and floor of the mouth missed a fact recorded in the first case, which would have substantiated his surmise that bony union of the jaw was only delayed in these cases. It was mentioned at the end of the account of Case 1. That when the patient was seen, six months after the operation and three months after leaving the hospital with a movable symphysis, the jaw was quite firm; in other words, bony union had then occurred, as a result of greatly improved general health and condition from residence in the country. This result renders it probable that bony union will be found to have taken place when the second case comes under observation, after a corresponding interval of time. The possibility of the halves of the divided jaw not uniting by bone is not touched upon in surgical works of established authority, nor is anything said about delayed union in cases published in medical journals. The point, however, is evidently important, for Sédillot's operation affords by far the freest access to the tongue and the adjacent structures of any of the ordinary operations on the tongue, and I do not think that it is a whit more dangerous than clipping out the tongue with scissors. Your comment may serve to direct attention to a neglected detail.

2. *Mr. Thomas Smith's successful case of supra-pubic lithotomy for a stone weighing 2½ oz.*—Whilst cordially congratulating Mr. Smith on the successful issue of this interesting case, I may be allowed to point out that it is doubtful whether the stone is the *largest* that has been extracted during life, nor is it even the *heaviest*. If Mr. Smith will refer to THE LANCET of Jan. 16th last he will find that Dr. W. B. Hunter of Londonderry reports a case of calculus weighing 25 oz. removed by Joseph Hunter, L.M.S., from a native in the Madras Presidency. The patient lived three days. Then there is Uytterhoeven's calculus measuring 16½ in. by 12½ in. in circumference. Moreover, the calculus which I was obliged to remove piecemeal from a pouch was *larger* but not so heavy, for it measured 13 in. by 10 in. in circumference. The extra *weight* of Mr. Smith's calculus appears to have been due to its centre of oxalates. He had the advantage of a patient only forty-three years of age, and of a calculus free in the cavity of the bladder; and I feel convinced that, if the latter had been the condition in my own case, a permanent recovery would have ensued. It is not my wish to detract one iota from the merit of Mr. Thomas Smith's operation, but merely to temper his not quite accurate superlatives.

3. *Strangulated umbilical hernia.*—In THE LANCET of Oct. 24th, 1885, I reported some cases of strangulated hernia treated by removal of the sac and omentum, and amongst them a case of strangulated umbilical hernia in a patient aged seventy. The account broke off on the fourth day after operation. The patient went on as well as possible, the wound healed, and she recovered completely. Further experience of this method of dealing with the sac and omentum has strengthened my opinion of its superiority over the mere relief of the stricture, which was all that was aimed at in the old operation.—Yours faithfully,

August, 1886. WALTER RIVINGTON.

THE LANCET.

LONDON: SATURDAY, AUGUST 14, 1886.

A CASE of considerable importance was tried last week at Liverpool before Mr. Justice CAVE and a special jury. It was a case in which an action was brought against Dr. IMLACH to recover damages for improperly performing an operation known as ovariotomy without giving the patient any intimation of the nature or result of such operation. Mrs. CASEY, the person operated upon, was forty years of age, had borne five children, and had enjoyed fair health up to the time of the operation in December, 1884. In March, 1881, she began to suffer some pain in the lower part of the abdomen, for which she was treated and cured. She suffered no pain thereafter until April, 1883. She then had another attack, and was again cured. In December, 1884, the pain returned, she became an in-patient at the Hospital for Women, Liverpool, and Dr. IMLACH performed "ovariotomy" upon her. Although the operation is described as ovariotomy, yet it is clear from the context that the operation was not what is usually termed ovariotomy, but oöphorectomy, BATTEY'S operation, or spaying. It is said to have been done for hæmatocele and hæmatosalpinx. At the end of the evidence for the defendant, the jury returned a verdict for the defendant without hearing counsel or judge. Dr. IMLACH is thus to be congratulated on the result of the case.

A court of law is not the place to elucidate scientific questions. Its methods are not adapted for such a purpose, but for the trial of narrow issues. Scientific evidence when given in court is cramped, one-sided, and often misleading, and necessarily so from the methods employed to obtain it. The gentlemen learned in the law, as well as the scientific witnesses, are not free to obtain or to give evidence, except on the narrow issue under consideration. Evidence which is regarded as unsuitable by either one side or by both sides may be omitted. The interest of this trial lies, however, far less in the narrow issue which the jury had to deal with than in the broad question whether the frequent and almost indiscriminate spaying of women suffering from diseases which are not fatal, and which are often only trivial, is justifiable. This great question was not touched upon, and indeed it is one not suited to be placed before a jury so long as the methods of the courts are such as they are at present.

Some astonishing statements were made in the witness-box—statements which are utterly at variance with the present state of knowledge of the subject. Mr. LAWSON TAIT stated that intra-peritoneal hæmatocele was fatal in 95 per cent. of cases, if left long enough, and in the majority of cases it was fatal in three hours if not operated upon. The judge interposed here, and said, "This woman had three previous attacks, and none of them were fatal, although treated medicinally and not surgically." Mr. TAIT, however, replied, "This is a case that is unique, and I have seen none like it." We can hardly understand his statement that 95 per cent. of cases of intra-peritoneal hæmatocele prove fatal, and that Mrs. CASEY'S case is unique. It is true that when the rupture of the sac of an extra-uterine pregnancy gives rise to hæmatocele, the condition is dangerous and fatal, but such rupture is not among the common causes of hæmatocele. Intra-peritoneal hæmatocele is a condition frequently met with; extra-uterine pregnancy is comparatively rare. Recurring intra-uterine hæmatocele, like the case of Mrs. CASEY, is not very rare, and it very rarely proves fatal; its tendency is to recovery. The danger accompanying it, however great it may be in theory, can be truly measured only by the results obtained by medicinal treatment. Measured in this way the danger is extremely small. There are not more than two or three institutions in the kingdom, and not one general hospital, in which it is the rule to treat intra-peritoneal hæmatocele by abdominal section.

In the evidence of Dr. GRIMSDALE, which was of a highly scientific character, one fact very important was stated—namely, that in the Liverpool Hospital for Women, 111 women were spayed during the past year, and 44 during the previous year.

The highest authorities in this country have justly condemned the frequent performance of spaying, and it is well known that such practice is limited to one or two towns in the kingdom. In America the operation has been performed with great frequency, but there pathologists and physicians have begun to question the frequency of disease of the uterine appendages calling for their removal; and they assert that ovaries are removed and called cystic, which are in reality typically healthy organs. That there are certain cases in which the operation is justifiable and called for cannot be denied; but the idea that such cases are common is entirely erroneous.

THE State of Medicine in the United States and of State Law as it affects Medicine, as a science and as a profession, are subjects of immense interest. Dr. BILLINGS' remarks on them, constituting the Address in Medicine of the British Medical Association, in lieu of that which was to have been delivered by the lamented Dr. FLINT, may be too long to be overtaken in a day by every reader of it. But it will well repay study. The subjects are of interest to us in more ways than one. The Americans are not the men to stand still in medicine, any more than in any other practical art. Already they have given us fair notice of sharp competition. In medicine proper, in surgery, in gynæcology, in midwifery, they more than hold their own. They come to Europe and are thankful and respectful learners in London, Paris, Berlin, and Vienna. But there is nothing in their respect which forbids them going beyond their teachers, or becoming teachers of us in their turn. In anæsthetics, in abdominal surgery, in lithotrity, in therapeutics they have had men of "light and leading," and fortunately have them still. This is one reason why Dr. BILLINGS' Address should be carefully considered, in spite of its somewhat undue length. Another reason is that under the new Medical Act we shall have to come to some very definite understanding with our brethren as to the value of their diplomas. We shall soon be asked to recognise some of them. Which? That is the question. It is therefore kind as well as opportune for Dr. BILLINGS to come amongst us and lay before us

frankly the state of the law, or the lawlessness of the States, in the matter of medical education and of medical diplomas.

Dr. BILLINGS is very candid. He tells us frankly that in his country there is great popular tolerance of, if not sympathy with, irregular and heterodox forms of medicine, and that the Medical Schools are so numerous and the examinations so defective, that when real sound tests are applied 70 or 80 per cent. of those tested are found wanting. It is not a little curious that the deficiencies of medical schools and medical Bodies in the United States have been made manifest exactly in the same way as they were brought to light here. The first effective demonstration of the imperfections of our examining system and of the education which preceded it was given by Dr. PARKES, who based his criticism on the experience of the special examinations for candidates for medical service in the Army and Navy. But for these we should never have obtained the great improvements already achieved, or the public inquiry leading to recent legislation. The Army and Navy Medical Boards in the United States have done an exactly similar service. They examine those already in possession of diplomas; their examinations are the most rigid tests of qualification in the States. And what is the result? Of the candidates who apply from 70 to 80 per cent. are rejected. Our own Army and Navy Boards now reject a very small proportion. This may partly be due to the fact that only the better class of students now venture to apply for these appointments. But it is largely because our Examining Boards, under the pressure of outside criticism, are really much more careful in their work and in the curriculum which they require to be observed by students. In this country the examining boards are by law made absolute judges of competency. Public opinion will back them in any reasonable and fair severity in the work of examination. In the States it is not so. Public opinion does not demand very strict or scientific tests of medical knowledge. In many States the law requires that on the examining boards there shall be a certain proportion of homœopathic and eclectic practitioners, and in the States generally there is little complaint—except from medical men—of that loose state of the law which allows charlatans and herbalists to vaunt their remedies, and the school examinations to be so loose that from 70 to 80 per cent. have to be rejected by the Army and Navy Medical Department. There is one other huge evil in the United States—the large number of schools, amounting to over eighty. These compete keenly with each other for students. They are not exacting in regard to preliminary education; their curriculum is short; their examinations are easy. Hence it happens that the profession is overcrowded and, consequently, less highly esteemed. There is a medical man to every 589 of the population, or about twice as many as in England. It is a serious thing when eighty bodies have an interest in drawing students and supplying them with diplomas. The very bodies that should protect the public are tempted to betray it and to flood the country with men whose incompetence may not appear in statistics, but must have terrible consequences in individual cases. We probably misapprehend Dr. BILLINGS, but if not, we must venture to differ from him in thinking that a practitioner may be good enough for one part of the country and not for another: good enough for a rural or malarious district, but not for an urban or a wealthy one. Quackery has at least one use—that of a foil to set off true and wise practice; but examining authorities should be strict. There will be quackery and incompetence enough, without any laxness on their part. It is not their function to ask how a sufficiently educated man is to be maintained; that is his look out. Their duty is to see that none but such men acquire diplomas. We must hope for another opportunity to notice other subjects of great interest in Dr. BILLINGS' Address.

IT is not a politic proceeding to visit a health-resort without previously ascertaining that it is really healthy. A moment's reflection must convince anyone that the fact of any particular place having a high reputation for its hygienic qualities is certain to expose its inhabitants and those who visit the locality to special risks. The convalescent from maladies of all classes, and more especially the "catching" diseases, always seek "change of air," and they are pretty sure to go, or be taken, to places, probably by the seaside, which are renowned for their restorative properties. Practically, therefore, just as a district naturally free from phthisical affections is sure to be crowded with the victims of lung disease, so a healthful locality is likely to be frequented by the unhealthy. There is no help for this, and the fact must be faced; but in so far as infectious or contagious diseases are concerned, there ought to be special measures taken to protect visitors to places of general resort for health purposes from the needless peril of unsuspected morbid poisons.

It is idle to rail against the lodging-house keepers as though they were greater offenders than others. As a matter of fact, it is the visitors who are most to blame. Does good and careful Paterfamilias, or the fond mother of the child, go frankly to the keeper of a lodging-house and say, "My little boy has just had an infectious disease, and I am bringing him to your house to get rid of the infection?" Certainly not. The parents are particularly careful not to mention the fact that the illness has been infectious or contagious. The servants are cautioned not to divulge the truth; and because human nature is selfish for its own interests and those of its immediate belongings, the health of subsequent visitors to the lodging-house in which the sick boy is located is disregarded. This is what happens frequently; and in the face of such occurrences it is unjust, we say, to blame the lodging-house keepers. They are only responsible for not divulging a fact which has been carefully kept from them, or which, if they know it, has been discovered accidentally. When a subsequent case occurs in the house, of course the lodging-house keeper *ought* to set aside personal interest, and starve rather than take in new lodgers, or at least disinfect his house; at the risk of his rival neighbours ascertaining the facts and publishing them to his disadvantage. All this he ought most certainly to do; but with the bad example set for him by his first lodger, it is not unlikely that he may leave the right and proper thing undone. Someone has said that sanitation is an affair of the individual; and it is simply true that if any serviceable reform is to be carried out, it must be accomplished by personal effort rather than by law-making, which generally means law-breaking, or, at best, law-evading.

There can be no question as to the expediency of making

it obligatory, in a legal sense, to notify the existence of *any* infectious or contagious disease to the local medical officer or to the sanitary authority of the district. This ought to be done without delay everywhere; but when so much has been accomplished, there will remain the real *crux* of the difficulty untouched. When a case of infectious disease is developed, the mischief of propagation has generally been some time in operation. To grapple with the evil at close quarters we need to give the lodging-house keeper a remedy against the person who brought disease into his house. When a case of infectious disease occurs, it should not be simply a question of reporting the existence of the disease, but of determining whence it came and who was the introducer. If it were made the duty of the medical officer of health to investigate the manner in which the disease had been contracted, and if the conclusions at which that official arrived were available as evidence in support of a claim to damages on the part of the lodging-house keeper, there would soon be an end of the cowardly practice of sending the infected, or probably infected, members of a family to a health-resort without the smallest care or precaution; and lodging-house keepers, having a prospect of compensation, would not hesitate to report the existence of infectious disease in their houses unless they were really themselves at fault, in which case the visitor who contracted disease should have his remedy against the peccant housekeeper. It is imperative that something should be done in this matter; and we venture to think that, to be effectual, equitable compensation to the party who has been exposed to risk through the carelessness of another should form part of the arrangement.

We do not desire to overstate the perils which beset those who go from home to seek health, but it cannot be disguised that the danger indicated is a very considerable one. It is not enough to consult the death-rate of a locality, and to assume the sanitary perfection of a district which does not happen to have had many deaths from zymotic disease. There are many maladies which do not directly kill. It would be interesting, though painfully so, to be able to tabulate the cases of disastrous illness distinctly traceable to the contraction of diseases at health-resorts which, having only an insignificant proportion of deaths from infectious disease recorded against them, contrive to keep up their character. In short, we should deal with disease rather than death, and to do this there must sooner or later be a complete and well-adjusted system for the registration of disease, applicable to all cases and in force throughout the country.

A long telegram was despatched to this country on August 6th by the correspondent to *The Times* at Venice as to cholera in North-Eastern Italy which it is by no means easy to understand. As is now well known, cholera, after prevailing for two years in various parts of Italy, reappeared in Southern Italy, where it has been and still is most fatal, and cases were reported about the same time as occurring in the town and province of Venice. Thence there has been a wide diffusion of the disease. To the east the extension is recorded as affecting certain port towns on the Austrian and Hungarian coast and the villages lying near them, but to the west and south it has been on a wide scale, making its way into a number of provinces as far west as Verona and as far south as Bologna and Ravenna. This disease in the north-east of Italy has already caused over 1800 deaths this summer, and in many places, as, for example, in Bologna and Ravenna, the fatality is at the rate of about 50 per cent. of the attacks.

But the correspondent in question, referring to the "commotion in the eastern provinces of Italy," finds as the results of his inquiries "confirmation of the doubts" he has felt, since he first entered the infected district, "whether there is any Asiatic cholera" there. We are at the onset bound to say that we can hardly conceive that any other malady could, under the circumstances afforded by the recent history of Italy, be mistaken for that disease, and this especially in view of the heavy mortality which is occasioned by it. But it is when the correspondent in question comes to explain what the disease may be apart from cholera that our greatest difficulty occurs. Speaking of what he regards as the reprehensible precipitation of the local authorities in regarding all sudden attacks of diarrhœa as cholera, and of the injury done by the consequent isolation practised, he instances what we assume to be a typical case. The case was one which, he alleges, was not Asiatic cholera, but one "rather of typhoid fever," and it is stated that in spite of the protestations of the physician who was called in, the patient was treated for cholera, and he had so far recovered within "two days" as to be released "as the physician predicted." Any more conclusive evidence than that contained in the last few words quoted from the telegram that the disease in question was not typhoid fever, as we understand that term, can hardly be imagined. Typhoid fever certainly is not a disease of which anyone having the most rudimentary knowledge of medicine would predict recovery in two days; but, on the other hand, a number of cases are met with during cholera epidemics as to which careful treatment for that disease does result in comparative recovery within a few days. In Venice, we admit the fatality is not now so great as it is in some other of the towns in the north-eastern provinces, but the disease, which has caused over 900 deaths in the province of Venice, must be regarded as a whole; and looking at it from that point of view, we fail to see that it is an "endemic rather than an epidemic," unless, indeed, the third year's course of cholera in the same country can be held to justify its being regarded as having become endemic. One explanation as to the readiness with which the disease is called cholera by the local medical men is stated to be that the Italian authorities allow a fee of 25 francs for a case of cholera, this sum being greatly in excess of the usual fee for ordinary medical attendance. But this explanation is obviously insufficient in the face of the fact that the disease which prevails at Trieste and Fiume and in the neighbouring villages is styled by the same name; neither does it account for the statement which is afforded by another correspondent of the same paper, to the effect that "cholera" is on the increase on the Dalmatian border and in Croatia. There have, however, been several suggestions that many of the symptoms usually associated with cholera have not been apparent in some of the towns affected, and it has elsewhere been remarked that the disease which exists has in many places been less fatal, and that it has been much more limited in its severity than epidemic cholera usually is; but, on the other hand, it is well known that cholera is a

disease which is more or less marked in its symptoms according to the circumstances in which it occurs, and according to the stage of the epidemic of which it forms a part; and although the disease, as it is prevailing in some of the towns in Italy, tends in some respects to resemble outbreaks of epidemic diarrhœa amongst adults, such as we have had recent knowledge of in this country, yet with the information as yet before us, we are unable to distinguish between the fatal disease which has prevailed in the south at Bari, Latiano, Francavilla, and now at Barletta, and that which is equally fatal in such towns as Bologna and Ravenna in the north-east. On the other hand, diarrhœal epidemics are not nearly so fatal as the least fatal of the outbreaks in the several towns of Italy, and where the signs of cholera are ill-marked it is far more likely that we may be witnessing a last stage of the epidemic of 1884-86 than that the epidemic is due to some other disease than cholera.

Annotations.

"Ne quid nimis."

THE REGISTRAR-GENERAL'S QUARTERLY RETURN.

IT is pointed out in the Registrar-General's Quarterly Return just issued, that the English death-rate during the three months ending June last was the lowest recorded in the second quarter of any year since the commencement of civil registration in 1837. The period prior to 1837 may, as regards trustworthy mortality statistics, be correctly described as prehistoric. The death-rate in England and Wales in the second quarter of the year fell below 20 per 1000 for the first time in 1880, and it is noteworthy that since that date the rate has only once (in 1883) reached that figure, while it has three times been below 19, the lowest rate being 18·0 in the quarter now under notice. The mortality last quarter in the chief town population, estimated at nearly 17,000,000, did not exceed 18·3, while in the remaining, and mainly rural, population of nearly 11,000,000 the rate was 17·5. Urban mortality was therefore as 104·6 to 100 taken to represent the rural mortality. The mean proportion of urban to rural mortality in the second quarters of the ten years 1876-85 was 113 to 100. This decline in the excess of urban mortality, especially in the largest towns, is one of the most marked, and at the same time one of the most satisfactory, features of the recent decline in the English death-rate. In the twenty-eight largest English towns, including London, with an estimated population of rather more than 9,000,000, the death-rate last quarter averaged 18·6, and was nearly 14 per cent. below the mean rate in those large towns in the ten preceding corresponding quarters; the decline in the general English death-rate did not exceed 10 per cent. The death-rates last quarter in these large towns ranged from 15·3 in Brighton, 16·6 in Birkenhead, 16·7 in Hull, and 16·8 in Bristol, to 23·9 in Portsmouth, 25·1 in Blackburn, 25·2 in Manchester, and 30·3 in Preston. Thus the Lancashire towns maintain their unenviable notoriety of excessive mortality, even in the present day of generally declining death-rates. Among the most noteworthy features of the Registrar-General's most recent mortality statistics is the remarkable decrease of zymotic mortality and the steady decline of infant mortality. As regards the former of these features, it should be specially noticed that those diseases no longer show the marked excess of mortality in the largest towns compared with that recorded in the remaining and mostly rural parts of England and Wales. The death-rate from the principal zymotic diseases last quarter was 1·55 in the whole of England and Wales; it was 1·81 in the seventy-eight largest towns, and 1·36 in the rest of England and Wales. This excess in the largest towns was almost solely confined to measles and whooping-cough, which diseases urban sanitation has not yet attempted to deal with by isolation. Small-pox was more fatal in rural districts and small towns, and the death-rates from diphtheria and "fever" were fully as high in the mainly rural districts as in the largest towns. This seems to point to the fact that sanitation is not yet in the rural districts and small towns what it has now become in most of the largest towns.

MEDICAL STUDENT LIFE IN LONDON.

THE ever-recurring question of supervision of the medical student in his work and at his play has again been revived by a letter from Dr. Evatt in *The Times*, who makes it an opportunity for unduly praising the care taken at the medical school at Cambridge as compared with the London schools. Dr. Evatt quite ignores the differences in the previous education and training of the average London student and the Cambridge undergraduate, and, forgetting the man, attributes all good or evil to the system. The tone running through Dr. Evatt's letter shows that he is not familiar with the vast changes in supervision and discipline in the London schools during the past twenty or thirty years, and he is apparently under the belief that idleness and riot are still allowed to go unchecked as in the days of his own pupilage. Bob Sawyers and Benjamin Allens are really nearly as extinct as the dodo, and medical students, socially and professionally, at work and at play, do not differ very much from other species of the genus student. By some authorities, not unconversant with their manners and customs, they are considered to be as gentlemanly in their behaviour and as earnest in their studies as even the theological, legal, or military student. A lad passing straight to a medical school from his ordinary school life merely passes from one stage of discipline to another. "Walking the hospital" is anything but standing at the front door in idleness, and for the first two years really means incessant work from nine till four or five in the dissecting-room, laboratory, or class-room, and Dr. Evatt is evidently quite mistaken as to the amount of discipline exercised therein. Attendance at some set lectures may be a little lax, but this is only because the student's work has become more and more practical every year, and because the increasing tendency is to lessen their number instead of insisting on a perfunctory attendance as in days gone by. Formal reports may not be sent home periodically by more schools than two, but school committees exist, we believe, in every London school, and they are not slow to enforce discipline or to warn the idler that he must work or else his parents will be asked to remove him from the school. Dr. Evatt seems really to believe that perpetual pupilship is a fact, and not a mere verbal phrase, but we should have thought that everyone who had given the subject some *study* was aware that this was always, as Mr. Bruce Clarke puts it, conditional on "the student's work and conduct being satisfactory to the hospital authorities and to the medical officers." There may be many reasons why the fees of the student should be paid for each class separately when he attends it, instead of in a lump sum, as is the present custom in London, but any supposed impossibility of getting rid of an idle student has never struck us as being concerned in the question. The difficulty of finding residences for medical students is sufficiently well known, and the eager desire of everyone connected with medical education to foster residential halls is shown practically by those who have built such rooms, and by other authorities who are trying to build them; but Dr. Evatt must surely be aware

that on such points as these London can hardly be fairly compared with Oxford and Cambridge. Does he know anything of student life elsewhere—say in Edinburgh, Glasgow, Aberdeen, or Dublin, or even in Germany? Do not the authorities of the London schools exercise as much social supervision over students as is done at other great centres of medical education?

THE CHOLERA EPIDEMIC IN SOUTHERN EUROPE.

THERE has been a severe recrudescence of cholera in Southern Italy during the week ending August 10th. Almost all news had ceased from the south, when on the 7th of the month information came to the effect that at Barletta, a port town to the north of Bari, there had been 132 attacks and 45 deaths during the previous twenty-four hours. At Barletta the disease has since that date been maintained with great severity, and in the four days ending the 10th, the total number of attacks and deaths there have been 536 and 217 respectively. At the same time, news has been received of an outbreak at Palo, and the bulletins as to cholera in Brindisi have been resumed. In the north-east of Italy there has been no extension of the disease further westward, but nearly all the towns and villages hitherto affected continue to record fresh attacks and deaths either daily or at intervals of a few days only, and in some towns the mortality is at a rate which is rarely exceeded during the worst periods of epidemic cholera in Europe. Thus, during the week we are dealing with, there have been 84 fresh attacks and 52 deaths in Bologna, 138 attacks and 62 deaths at Ravenna, 53 attacks and 22 deaths at Verona. The disease has also been steadily maintained at Chioggia, Castelfranco, Verona, Padua, and other places. In Venice the mortality is comparatively small. The daily record of attacks in that city have varied from 4 to 11, and the deaths have only exceeded 1 on the 7th, when 5 fatal attacks occurred, the total weekly record being 46 attacks and 10 deaths. In all, there have been recorded from Italy during the week ending Aug. 10th 1320 attacks and 484 deaths. In Austria the definite news as to cases of cholera is still limited to Trieste and Fiume. At Trieste there have been 26 cases and 16 deaths, and at Fiume 4 cases and 2 deaths. This, however, takes no cognisance of the surrounding villages which have previously been announced to be infected. This local prevalence of cholera has led to the departure from Trieste of no less than 15,000 persons. Four cases are also reported at Naples, the persons attacked having come from infected districts. The disease, again, is stated to be increasing in the direction of the Dalmatian border and in Croatia.

CACHEXIA STRUMIPRIVA.

THE records of cases in which a condition resembling that of myxœdema has developed after extirpation of the thyroid gland are increasing. The latest is an account furnished by Dr. Hans Schmidt of the Augusta Hospital, Berlin (*Berl. Klin. Wochensch.*, 1886, No. 31). It appears that during the five years 1880-86, twenty-five cases of thyroidectomy have occurred at this hospital, mostly under Professor Küster's care. Of these, six were cases of total extirpation, seventeen of unilateral, and two of malignant growths. All the unilateral cases survive, and not one of them has developed any ulterior symptoms, the interval since operation varying from six months to four years. Of the cases of total extirpation, two died of hæmorrhage following operation, another died about a year later from phthisis, another patient, a young girl, was perfectly healthy several years afterwards, and a fifth required tracheotomy six months after the thyroidectomy on account of paralysis of the abductors. In only one case had the manifestations of cachexia strumipriva arisen. This was a lad who, at the age of fourteen years, was admitted in July, 1883, suffering from an enormous goitre, which caused considerable dyspnœa. The operation had to be done in two sittings, and on each occasion tracheotomy was necessary, the cannula being removed the day after. After the lapse of two years and three-quarters he was brought to the hospital by his father, with the statement that ever since the operation he had gradually deteriorated both mentally and physically, leading a listless, indolent life, taking no interest in anything. The change in the lad's physique was most striking, and thoroughly accorded with Kocher's description. The body was undeveloped, the muscles were lax, the skin flabby and of a yellowish colour; there was slight œdema of the cheeks and back of the hand; the mucous membranes were pale the testes very small; no splenic enlargement existed. The trachea appeared to be very thin, and there was no trace of a thyroid gland. The head was relatively large, and hair scanty; speech slow and drawling; aspect stupid and dull. He walked slowly, and was easily tired. The larynx and urine were normal. His memory had become defective.

SCHOOL BOARD CONUNDRUMS.

SURELY Mr. Endean could not have been serious when, at the last weekly meeting of the School Board for London, he cited as questions put to pupils in Board schools the following conundrums:—"1. What would be now thought of crusades, trial by ordeal, and Smithfield fires? 2. How may a current of electricity be produced, and what magnetic, chemical, and mechanical effects may be brought about by means of such a current? 3. A sphere weighing 10 lb., and having a radius of 7 in., hangs by a cord from a point in the wall, and leans against the wall. The point of contact of the sphere and wall is 2 ft. below the point of suspension. Find the length and the tension of the cord. 4. State all the conditions you know of which affect the climate of any place. 5. Why are the following pairs of words called 'doublets': example and sample, faction and fashion, diamond and adamant? 6. State precisely how you would proceed if you were required to prepare a sample of pure hydrogen. 7. Write out examples of a definition, an axiom, a problem, and a theorem. 8. Describe the grievances which led to the Americans asserting their independence. 9. It is said that 'the sun never sets on the Queen's dominion.' Taking a line from London eastwards, denote the points which would make this statement fairly correct. 10. Explain the terms—motion, velocity, acceleration, momentum, and energy." If such questions were really put, we venture to think the lowest abyss of dementia must have been reached by those who preside over the vagaries of our educators. No wonder Sir James Crichton Browne found the children had headaches.

EASILY SATISFIED.

ON the 4th inst. an inquest was held by Mr. William Carter on the body of a girl, a shirt-maker, aged sixteen years, who up to the time of her death had resided with her parents. The deceased had enjoyed good health till the 29th ult., when she was attacked with sickness and pains in the abdomen, and had to return home from her place of employment. On the following day she kept her bed and the sickness continued, and at midnight the pains increased to such an extent that it was thought prudent to send for medical assistance. No doctor, however, could be obtained until six o'clock on the 31st ult., when Dr. Farr, through the agency of the police, attended and pronounced life extinct. At the inquest Dr. Farr deposed that the cause of death was very obscure, and he could not express any opinion without a post-mortem examination. The deceased was a fine and fully-developed young woman, who had enjoyed good

health, and the body was well nourished. There was nothing to indicate disease of the heart, brain, or any other organ, and he was of opinion that death was due to some irritant in the stomach. A sister of the deceased was recalled, and stated that the unfortunate girl had always suffered from constipation. In spite of the mystery attaching to the death, and the opinion of Dr. Farr as to the presence of an irritant, the jury after a short deliberation returned a verdict of "Death from natural causes, arising on inflammation of the bowels." We have no hesitation in expressing the opinion that the verdict was unsupported by medical evidence, and that in the interests of the public Mr. Carter should have ordered a post-mortem examination to be made.

THE INFLUENCE OF SANITARY WORKS AT MERTHYR-TYDFIL.

MR. DYKE, the well-known health officer to the town of Merthyr-Tydfil, has now completed a series of twenty annual reports; and in so doing he makes a summary showing the proportion of deaths per 10,000 persons living during a series of groups of years. The first period is that from 1845 to 1855, before any sanitary works were commenced; the second includes the six years 1856-61, during which paving works and removal of nuisances were attended to; the third relates to the four years 1862-65, whilst the works specified were still being carried out, and whilst water was also being laid on to the houses; the fourth includes the ten years 1866-75, when the water-supply was perfected, whilst the sewers and drains were being laid and whilst the sewage disposal was being completed; and a fifth deals with the ten years 1876-85, when the whole of these completed works were in operation. The table shows a gradual and continuous reduction of the death-rate from all causes from an average of 332 per 10,000 in 1845-55 to one of 231 in 1876-85, the proportionate mortality of infants under one year of age being reduced from 80 to 45 per 10,000. The rates from the contagious fevers—measles, scarlet fever, and whooping-cough—do not seem to have been in any way affected by sanitary improvement. This we were prepared for; but it is curious that the same applies to diphtheria. Probably this is due, not so much to the fact that this latter disease is independent of sanitary conditions, as to the circumstance that diphtheria has of recent years been much more widely diffused in this country than it was during the earlier periods referred to in the table. On the other hand, there has been a marked diminution in the other forms of "fever." "Continued fever" has practically ceased to exist as a separate disease—a circumstance doubtless due to improved nomenclature; and the mortality from typhoid or enteric fever has fallen from 21 to 3 per 10,000. The death-rate from infantile diarrhœa has also fallen from 11¼ to 4 per 10,000; and the average age at death has increased from seventeen years and a half to twenty-seven years and a half, a clear gain of ten years of life. It will be observed that in making these comparisons Mr. Dyke is following out the plan adopted by Dr. Buchanan in 1866, when he reported on the results of the adoption of sanitary works in many of our large towns, including Merthyr-Tydfil, and hence it is appropriate that the information as to the results of the drying of the subsoil by the construction of sewers should be specially dealt with and brought up to current date. The influence of such drying has brought about a reduction in the phthisis death-rate from 38 to 22 per 10,000; but acute and chronic bronchitis and pneumonia have during the same period become more fatal, the corresponding rate for this group of affections having risen from 33 to 45—a result due, in the opinion of Mr. Dyke, to the continued occupancy of damp and unventilated dwellings. On the whole, this summary affords the most convincing proof that properly planned and well executed sanitary works result in a vast decrease in sickness and death, and by producing healthiness and increased duration of life they become a source of profitable income to the communities affected by them.

CRUSHING THE GRANULATIONS IN TRACHOMA.

DR. KRAMSZTYK, writing in the *Gazeta Lekarski*, advises a method of treating granular lids or trachoma which was proposed by Dr. Wicherkiewicz, and which consists of a forcible crushing of the granulations. The eyelid is everted and held by an assistant, and is then subjected to pressure between the two thumb-nails, the operator moving his thumbs to and fro so as to act on as much of the eyelid as possible. Where the granulations cannot be reached in this way, such as those situated at the canthi and on the plica semilunaris, they are pricked with a needle, and then crushed by means of a pair of forceps or some other suitable instrument. The operation is very painful, and cocaine seems to be of little use. Under chloroform, the whole of the granulations can be crushed at a single sitting. Otherwise the length of time and the number of sittings required to effect a cure depend on the abundance of the granulations and the patient's power of endurance. Where other disease of the conjunctiva exists, it must of course be attended to, and different measures adopted. The after-treatment consists in the prolonged application of cold water dressings to the eye.

THE MEDICO-PSYCHOLOGICAL ASSOCIATION.

THE annual general meeting of this Association was held in the rooms of the Medical Society, 11, Chandos-street, on August 9th, under the presidency of Dr. G. H. Savage. At the opening of the proceedings there were many expressions of deep regret at the recent and somewhat sudden death of Dr. Eames, the president for the past year, under whose auspices the previous annual meeting had taken place at Cork, and a resolution of sympathy with his family was unanimously adopted. Dr. F. Needham was elected to be president for the year 1886-87. Some discussion arose in reference to the examinations for the certificate now granted by the Association of competency in psychological medicine. Among other modifications, the fee was lowered to three guineas, and it was decided that the examination should be open to anyone who was a student in medicine and of age; that there should be no restriction as to his being qualified before applying for the certificate, but that, if successful, he should not receive it until he was registered. It was decided that the next annual meeting should be held in London. At the afternoon meeting the President read an address on the subject of the pathology of insanity, which was followed by a discussion in which Drs. Clouston, Conolly, Norman, Hack Tuke, and Rayner took part. The members afterwards dined together at the "Ship" at Greenwich.

HOUSE-BOATS AND THE THAMES CONSERVANCY.

OUR report on the pollution of the Thames at the Henley Regatta has been greeted with marks of approval from all quarters. We have received innumerable letters confirming all the evils our Commissioner denounced, and, finally, we are pleased to note that the Thames conservators are seeking to deal with the question. Their efforts, unfortunately, do not as yet promise a very brilliant result. We are told that in regard to house-boats and launches the conservators appear to rely on the requirements of registration to prevent the pollution of the river. Certainly, as the *Law Journal* points out, the conservators could not be compelled to register a boat which obviously, from its construction,

broke the sanitary law established by statute for the Thames. For our part, we fear that it will complicate the issue if the vexed question of numbering and registering boats be mixed up with the imperative necessity of enforcing the sanitary law. If a pickpocket plied his industry on board a house-boat, or if a quarrel led to a case of homicide, the police would not wait till the boat was numbered and marked, according to some new regulations, before proceeding against the culprit. Then why should the inhabitant of London wait till house-boats have "painted upon each bow, and upon each quarter, either the register number or the name" of the boat before the water he is compelled to drink is protected from a frequent and dangerous contamination? Further, supposing that in the course of time the registering is effective in abolishing the closets on board these boats, this will not prevent the throwing overboard of all manner of refuse and, perhaps, of soil. Where a great number of floating dwellings collect together, as in the event of a regatta, a scavenger-boat still remains a necessity. When, on the contrary, the house-boats are scattered in all directions, then watch should be kept and prosecutions instituted against those who are detected and can be proved to have contaminated the river. The law in such cases inflicts very severe penalties. There is not so much need of new regulations as of an organised service for carrying out the existing law.

NEW MEDICAL GRADUATES FROM HEIDELBERG.

SOME of our correspondents are being alarmed at the prospect of an immigration of foreign graduates under the new Medical Act. It will be interesting to see the answer that will be given by the Council to the application of Sir Henry Roscoe, of Manchester, and Professor William Thomson, of Glasgow, when they apply to have the degree of Doctor of Medicine, which they have just received at Heidelberg, registered. It does not do to be too critical about honours distributed on such a rare occasion as the 500th anniversary of a university, and it is perhaps as easy to acquiesce in Sir Henry Roscoe and Professor Thomson receiving medical degrees as in the Grand Duke receiving the degree of Doctor of Theology. These somewhat fantastic actions notwithstanding, the jubilee seems to have been a great event, upon which Germany generally, and Heidelberg especially, may be heartily congratulated.

PRESERVATION OF FRESH FISH.

OF late years we have been accustomed to associate economy in the preservation of food with colonial or transatlantic enterprise. It is therefore the more encouraging to learn that Europe is equal to inventive progress in the same direction, and of this we have apparently a genuine proof in the method of preserving fresh fish introduced by Mr. August R. Roosen of Hamburg. By his process, which is a simple one, the fish when caught are enclosed in steel barrels each capable of accommodating 300 lb. weight, immersed in a 3 per cent. antiseptic solution of boracic acid, tartaric acid, and salt in water, which is forced in by means of a hydraulic hand-pump, while air is simultaneously expelled. An air-tight lid closes the cask, and the bung-hole is a valve to which the pump is attached when in action, and which at a certain stage is closed by internal pressure. It is also satisfactory to find that a year's experience has proved its practical efficiency, at all events in the hands of the introducers. Meat is stated to have been preserved by the same process. On board of the larger fishing craft the plan appears likely to answer well. One or two points in connexion with its working will require careful regulation. With regard to the water to which the antiseptics are added, if this is to consist of sea-water as might naturally be expected, it will still be necessary for coast fishers to be careful as to its purity from river or port refuse. It will also be necessary to guard against the overcrowding of fish. If this should happen, even powerful antiseptics will be of little avail, since perfect exclusion of air is hardly possible. We hope that future use will justify the promise of this novel and ingenious experiment.

PLUGGING THE TRACHEA IN LESIONS OF THE PNEUMOGASTRIC.

IN an article in the *Nordiskt Mediciniskt Archiv*, Dr. Jens Schou of Copenhagen discusses at some length the treatment of traumatic lesions of the pneumogastric nerve by means of permanently plugging or tamponing the trachea. Dr. Schou gives a succinct description of the doctrine propounded by Traube, that the pulmonary affection caused by section of the pneumogastric nerve is a pneumonia by aspiration—a theory which has lately been supported by other observers, more especially Gärtner. It appears that with animals the unilateral section of the pneumogastric or of the recurrent nerve is generally harmless; but in the human subject it causes pneumonia by aspiration. The reason seems to be that in animals the sections are effected without complications, whilst in men they are as a rule the result of some serious operation capable alone of causing a state of collapse from which pneumonia by aspiration might result. Here, one of the vocal cords is paralysed, which serves to increase the effect of the lesion. The treatment indicated is, then, permanent tamponing of the trachea till the end of collapse, by which time the healthy cord will be accustomed to replace the diseased one. Below's method—namely, tamponing above the cannula—is recommended, an india-rubber ball above. Dr. Schou, however, prefers to introduce a tampon of some antiseptic material such as iodoform gauze. A tampon of this kind is easily applied by means of a cannula open above. If it be necessary to cut the pneumogastric or recurrent nerve, tracheotomy and tamponing should be immediately resorted to, in order to prevent the development of pneumonia by aspiration. Should some time have elapsed before pneumonia by aspiration fully developed has been discovered, it is still necessary as quickly as possible to do the tamponing in hopes of arresting the progress, for in these cases the nerve may be paralysed for some time.

OPIUM POISONING.

AN inquest was held a few days ago on the body of a woman, the wife of a labourer, who committed suicide by taking an overdose of laudanum. The husband stated that about six weeks ago she nearly died from taking the same medicine. On the day of her death, quite early in the morning, he was awakened by his wife, who told him she had swallowed "some more of that stuff again." She was removed to the infirmary, where a few hours later she died. The coroner strongly condemned the system by which laudanum and other deadly poisons could be obtained without question, and the jury after some deliberation returned a verdict that the deceased committed suicide whilst in an unsound state of mind. It was mentioned in the course of the inquiry that the deceased had taken one ounce of laudanum. With regard to this, it is well known many people have recovered after taking very much larger doses of laudanum. We would also point out, in the absence of the old-fashioned stomach-pump, a piece of common indiarubber gas-tubing, fitted with a glass funnel by which it could be filled with water, would suffice not only to empty the stomach of its contents, but to wash it out thoroughly. The use of apomorphine as an emetic is now generally recognised, and it is to be regretted that in this case it was not resorted to for the evacuation of the poison. Coffee in the form of an

enema, with hypodermic injections of atropine repeated from time to time, are the true physiological antidotes; whilst the cold douche, and electricity or massage to the extremities, would act as valuable accessories.

OFFICIAL CHOLERA MEMORANDUM.

IN view of the recent serious extension of cholera in Italy and the appearance of the disease in certain Austrian ports of the Adriatic, the Local Government Board have drawn the attention of sanitary authorities in this country to the memorandum which was issued in July, 1885, on Precautions against the Infection of Cholera, by Dr. Buchanan, their medical officer, and they again urge upon authorities the importance of continuing, without intermission, to take all measures within their power for maintaining their districts in a state of security against the infection of that disease. The memorandum in question, after explaining the circumstances under which cholera habitually spreads in this country, draws especial attention to the need for maintaining all water-supplies free from the risk of pollution, for securing the systematic and frequent removal of all filth and refuse from the vicinity of dwellings, and for maintaining a state of cleanliness everywhere and under all circumstances; and, lastly, it draws attention to the importance of remembering that any pains taken and costs incurred for the purposes referred to cannot, in any event, be regarded as wasted. Indeed, the sanitary improvements which would justify a sense of security against any apprehended importation of cholera would, to their extent, give amply remunerative results in the prevention of those other diseases. This is eminently true, and some of the most permanent works which have conduced to the saving of human life in this country have resulted from efforts to cope with anticipated advents of cholera.

DEATH OF DR. ROBERT FOWLER.

WE regret to have to announce that Dr. Robert Fowler, of Bishopsgate-street Without, and Old Burlington-street, died at Hampstead on the 7th inst. from pyæmia at the age of fifty-eight. He was M.D., and M.R.C.P. Edin., M.R.C.S., Associate of King's College, London. He was one of the Examiners to the Society of Apothecaries, late Manager to the Metropolitan Asylums Board, late President, Librarian, and Orator to the Hunterian Society, and author of a "Medical Vocabulary." He exposed the celebrated case of the Welsh Fasting Girl, on which he published a book, entitled "Observations on Death from Starvation." Dr. Fowler was a frequent contributor to the medical journals, and was much esteemed by wide circle of professional friends, as well as by a large *clientèle*.

MATRON v. MEDICAL STAFF.

SINCE alluding in a recent issue to the unfortunate state of affairs at the Blackburn and East Lancashire Infirmary, which has led to the resignation of the entire medical staff, we have learnt further particulars, which only serve to confirm our view of the arbitrary interference of the majority of the Board of Management with a question which belongs solely to the medical authorities. For some time past the medical staff have felt the need of having a second qualified resident at the infirmary, but the board have hitherto declined to entertain the proposal on the score of expense. The creation of a vacancy in the office of dispenser led the staff to suggest the appointment of a junior house-surgeon and dispenser; but since the use of the former title would involve a change of bye-laws, it was recommended that the dispenser should be medically qualified. In desiring to have a second qualified resident the staff acted, it seems to us, with regard to the comfort and welfare of the patients and the proper working of such an institution. They, and they only, could possibly be judges of what was needed in this direction; but a majority of the board (twelve to ten) rejected the proposal, one argument which appeared to have most weight being that the matron had objected to such an appointment, and had threatened to resign if it was made. We are seriously assured that the fear of losing the services of the matron was the principal reason assigned by the majority. If that be so, we can only express surprise at the manner in which a recommendation of the medical staff has been set aside, and trust that the Board of Management will take speedy steps to reverse a decision which is calculated to be disastrous to the welfare of the institution.

SPURIOUS CHARGES AGAINST MEDICAL MEN.

MR. JUSTICE FIELD has done loyal service to the cause of justice, and incidentally he has done good service to the medical profession, by sentencing a man who, to extort money, threatened a medical man with a ruinous charge. It is intolerable that a class of the Queen's subjects who live by their honour in an especial sense, and to whom any imputation on their morality is an irreparable injury, should be exposed to charges and threats of charges which are incited by dishonest greed or malice. Women and men are unscrupulous in what they say or do against medical practitioners, and the more kindly and generously they are treated the greater is the peril from their black ingratitude. The medical practitioner threatened in this case acted with courage and sagacity. He placed the matter at once in the hands of the police. It would be well if every medical man resolved to pursue the same wise course. The moment a charge is made, however vague it may be, let criminal proceedings be instituted. It is useless bringing actions at law. Treat the offence as a crime.

LIGATURE OF THE SUBCLAVIAN ARTERY.

AT the third meeting of the Italian Surgical Society Dr. Lampiasi reported two cases in which he had successfully tied the subclavian artery, after failure of ligature of the axillary under the clavicle. In the discussion which followed a case was referred to in which, two years ago, Dr. Piccinini, at the Ospedale della Consolazione in Rome, tied the subclavian just outside the scaleni for wound in the highest part of the axillary artery. The result was most satisfactory. (*Gazzetta degli Ospitali*, August 4th.)

TOWN REFUSE.

MR. JOHN BRAYE, a member of the Kensington Vestry, has moved for a select committee to report on the practicability of taking road-sweepings and dustbin refuse thirty miles into the country and giving it to the farmers free of cost; and he has requested, through the public press, information from farmers, surveyors, and others. Mr. Braye is evidently a gentleman who is not disposed to trust to contractors for the performance of the important duty of scavenging, and we shall await with interest the publication of the report of his committee, for the reason that the disposal and utilisation of refuse are evidently not to be allowed to depend upon questions of profit. If Kensington, like some other parishes, possessed a water-way, the cost of removal would not be so great as where dependence must be placed upon roads alone. Farmers will gladly utilise road sweepings at certain periods of the year, but for the rest it is necessary to find some place of deposit; and with regard to this, it is essential that it shall be far removed from all dwelling-houses. The subject could be dealt with much

more economically by an authority acting for the whole metropolis; and it is possible that this conclusion may be the outcome of the report of the Kensington Vestry.

MEDICAL REGISTRATION.

ONE good, if incidental, effect of the new Medical Act may be anticipated. As medical men, under it, are to have the power of voting for a representative in the Council, they may be expected to be more anxious about their own registration, and more careful in forwarding to the Registrar any change of their address. It is important, before the time of the election in November, that all errors of the Register be corrected and all registrations be complete. The Registrars of the several Branch Councils are doing their part in this matter. They are sending to each registered practitioner, by post, a printed statement on the importance of registration, with a copy of his own particular registration, for any correction which may be needed. Every practitioner should give this matter his immediate attention, and return the slip, with his affirmation of its correctness, as required by the form. Those who have been erased from the Register under Section 14—generally persons who have changed their address without informing the Registrar—should immediately send the necessary information, with a request to be restored to the Register.

REVOLVER BULLET LODGED IN THE BRAIN; RECOVERY.

AT the Society of Surgery of Paris, on May 26th, M. Prengrueber presented a man who had fired a revolver at the middle of his temporal fossa. The ball, seven millimetres in diameter, lodged in the brain. The three days following the accident the surgeon abstained from interference, as the only symptoms were general prostration, with lowering of the temperature. Epileptiform attacks having occurred on the fourth and fifth day, M. Prengrueber exposed the cranial wound and removed several bony spicules, which had penetrated the brain. A stilet having failed to detect the bullet, though passed along its course to a depth of five centimetres, nothing else was done. The epileptiform seizures did not recur, and the patient left the hospital at the expiration of a month without any cerebral complication.

THE EPIDEMIC OF ENTERIC FEVER AT SHOREHAM.

THE epidemic which was announced at Shoreham and at Lancing College is now stated to have been due to the consumption of milk from a dairy in Shoreham, where a well liable to pollution was allowed to be used as the water-supply. Shoreham has before this been liable to the same disease. The extension to Lancing College was due to the occasional use, during some cricket matches, of cream which was brought from the Shoreham dairy to Lancing to be served up with strawberries. At Lancing College the outbreak is over.

THE HOURS OF TRAMWAY MEN.

THE directors of the North Metropolitan Tramways Company have little or no sympathy with the talk about "slavery" and overwork among their *employés* to which many of the London public are addicted. Thirteen and a half hours per day of continuous work, during a week of ten days, with meals taken on the car, they seem to regard as matters of no great moment. We do not agree with them. Statistics may not perhaps be sufficiently exact to show how much health per annum is lost under these arrangements. That the loss is considerable we do not doubt. The system is one of unthinking and unwholesome hurry, and cannot fail to balance its money profit by a culpable and extravagant waste of human working power. Snatched meals are condemned by an all but universal trade custom, while the ten-day labour period has been tried before and has failed, even under the daily working conditions of the last century, which were probably far easier than our own.

THE ODESSA MEDICAL SCHOOL.

DIFFICULTIES of a pecuniary kind are at the very outset interfering with the commencement of the proposed medical school in Odessa. The rector of the university having applied to the Finance Ministry for £1000 for the purpose of enabling the architect to visit various foreign universities, and so to perfect his designs for the clinic and the scientific institutes, laboratories, &c., has been met with a *non possumus*. The municipal authorities, too, do not seem to be as complacent as was expected regarding the site, for they have refused the piece of ground upon which the university professors had set their hearts for the Anatomical Institute. It is to be hoped, however, that in course of time all these difficulties will have been arranged, and that Odessa will have the complete medical school which is so much required in South Russia, and for which so large a city is eminently adapted.

DIRECT REPRESENTATIVES.

DR. B. W. RICHARDSON has issued an address, presenting himself as a candidate for the office of direct representative of the registered practitioners of England and Wales. We understand that he has come forward on the invitation of a large general committee. Dr. Dolan, of Horton House, Halifax, has also issued an address. Dr. Dolan bases his claims on the facts that for seventeen years he has been a Poor-law medical officer, and for twenty-one years a general practitioner. It will be seen that the British Medical Association decline to act as a body in the way of nomination. We think this both wise and in good taste on the part of the Association. We are informed that, in addition to the list published last week, numbers of representative men in every district have signified their intention to support Dr. Glover's candidature.

THE SANITARY CONGRESS AT YORK.

IN connexion with the meeting of the Sanitary Institute in York next month (from the 21st to the 25th), under the presidency of Sir Spencer Wells, it is proposed to hold a conference of medical officers of health on the 22nd, in which, among others, members of the Yorkshire Association of Health Officers will take part. The subjects already decided upon are: the Appointment and Tenure of Office of Medical Officers of Health; Free Hospitals for the Treatment of Infectious Cases; and Local Government for Counties in relation to Sanitary Questions. It is anticipated that the conference will be well attended. The Health Exhibition, including sanitary apparatus and appliances in connexion with the Congress, will be held in the Yorkshire Fine Art and Industrial Institution Buildings, St. Leonard's-place, from Sept. 21st to Oct. 16th.

THE VOLTA PRIZE.

Le Progrès Médical (Aug. 7th) reports that the French Minister of Education has just fixed the date of competition for the Volta Prize. It is of the value of £2000, and was instituted by a decree dated June 11th, 1882, in favour of the author of a discovery which shall render electricity economically useful in one of the following applications:—As a source of heat, of light, of chemical action, of mechani-

cal power, as a means of transmission of despatches, or in the treatment of disease. The competition will remain open to June 30th, 1887, and the prize will be awarded the following December. Scientists of all nations may compete. A commission, nominated by the Minister of Education, will be charged with the examination of the discovery specified by each competitor, with a view to determine if it fulfil the required conditions.

FOREIGN UNIVERSITY INTELLIGENCE.

THE following vacancies in Spanish university professorships are officially announced:—Santiago: the chair of surgical anatomy, operations and bandaging. Seville: Cadiz Faculty of Medicine, the chairs of medical pathology and therapeutics. Saragossa: the chair of anatomy. The salary attached to each of the above chairs is about £140 annually.

There are three candidates for the vacant surgical professorships in Graz—viz., Professor von Winiwarter of Liège, Professor Wölfler of Vienna, and Professor Nicoladoni of Innsbruck. In Munich Dr. Posselt has been nominated Extraordinary Professor of Dermatology, and Dr. Bezoldt Extraordinary Professor of Otology.

The long-expected opening of the Siberian University at Omsk will have to be still further delayed owing to the impossibility of obtaining professors in the legal and medical faculties.

THE INTERNATIONAL MEDICAL CONGRESS.

WE were in error in stating that Sir James Paget is likely to attend the International Medical Congress. We may, however, still hope that one who would be so much missed will find his way to Washington.

ON the 10th inst. the death occurred of Mr. George Busk, in the seventy-eighth year of his age, after a lingering illness. The deceased became a member of the Royal College of Surgeons in 1830, and in 1843 was selected to receive the Fellowship of that institution. He was elected a member of the Council in 1863, and in 1871 was chosen president of the College. He was a Fellow, and had twice been vice-president of the Royal Society, and also a Fellow of the Linnæan, Geological, and Zoological Societies. Mr. Busk was a trustee of the Hunterian Museum, a member of the Senate of the University of London, and for some years acted as examiner in comparative anatomy and zoology to that university. At the time of his decease Mr. Busk had just completed an elaborate report on the zoophytes found during the expedition of the *Challenger*.

DR. R. J. MANN, whose death at the age of sixty-five has recently been announced, was well known in scientific circles in London. He was a member of the Council of the Society of Arts, for three years President of the Meteorological Society, and was a member of the Astronomical, Geographical, Photographic and other societies. In early life he held a Government appointment in Natal, where he served as head of the Education Department and medical officer for many years. Dr. Mann was a popular and prolific writer. Many of the recent scientific articles in the *Edinburgh Review* were from his pen, and he was a frequent contributor to several magazines and reviews.

PROFESSOR WEICHSELBAUM has been given space in the Vienna Anatomical Museum for the accommodation of his class in pathological histology.

THE death is announced of Dr. Frank Hamilton, the eminent surgeon of New York.

THE lectures on Darwinism, which Professor Mathias Duval delivered at the Paris School of Anthropology, have just been published by Delahaye and Lecrosnier.

ON Monday next, M. Chevreul, the famous French chemist, will complete his hundredth year, and the Parisians will celebrate the event by a grand fête.

BRITISH MEDICAL ASSOCIATION.

FIFTY-FOURTH ANNUAL MEETING,

HELD AT BRIGHTON, 1886.

ALTHOUGH the weather on the opening day of the meeting—Tuesday, August 10th—was not at first very propitious, the number of members who thus early appeared on the scene augured well for the probable success of the meeting. An unusual number of eminent foreigners were among those early arrivals, including Professor Charcot, of Paris, and Dr. Nathan Davis, the President-elect of the International Medical Congress to be held in Washington in September, 1887. Certainly no pains had been spared by the Municipality and medical profession of Brighton to welcome their visitors. The Royal Pavilion was placed at the disposal of the Association, so that the large general meetings could be held in the dome and the sectional meetings in the various apartments of this curious but interesting building. A museum of pathological specimens, pharmaceutical preparations, surgical and scientific instruments, &c., was opened in the Corn Exchange, which abuts on to the dome; whilst in the Museum of Science and Art adjoining the Pavilion there was a most admirable collection of bacteriological apparatus, cultivations of micro-organisms, microscopical preparations, and photo-micrographs exhibited by Mr. Edgar Crookshank in connexion with the Section of Public Medicine. Few places could be better adapted for such a purpose, whilst the proximity to London has done much to bring many to spend the week on the coast. An admirable guide-book, compiled by Mr. Friend, was presented to every member of the Association.

The Council were entertained by the Mayor at a banquet on Tuesday evening.

The First General Meeting was held on Tuesday afternoon in the Dome. The chair was taken by the retiring President, Dr. W. T. Edwards (Cardiff), who, after a few words expressing his hearty thanks for his election last year, and his hope to continue an active member of Council, said that he had great pleasure in handing his office over to Dr. Withers Moore, who would certainly well discharge its duties.

The PRESIDENT, in taking the chair, offered a hearty welcome to the Association in the name of the municipal authorities and the medical profession of Brighton. He mentioned that there were a very large number of distinguished visitors present, especially from America, including Dr. N. S. Davis, the President of the forthcoming International Medical Congress. He trusted that the meeting would be a pleasant and prosperous one, and he felt sure that socially and scientifically it would take a high rank.

A vote of thanks to the retiring President and a motion that he be elected a Vice-President for life was moved by Dr. Waters, seconded by Dr. Chadwick, and carried by acclamation.

The Report of the Council was then presented by the President of the Council, Sir B. Walter Foster, M.D. It began by alluding to the fact that since the Association last met in Brighton, in 1851, the population of the town had increased from 65,000 to 107,000; whilst the Association, which numbered 1200 members then, has at present nearly 12,000 members, and an invested capital of upwards of £22,000. New branches of the Association are to be formed at Limerick, Bermuda, Ceylon, Calcutta, and at Oxford. The labours of the various committees

were reviewed. The Medical Reform Committee, presided over by Dr. E. Waters for eighteen years, had accomplished its work by the passage of the new Medical Act, and a tribute of praise was accorded to Dr. Waters and to Sir B. W. Foster for the share taken by them in this work, especially in respect to the number of direct representatives allotted to England. The Parliamentary Bills Committee had rendered assistance in amending the Lunacy Acts Amendment Bill, which passed the House of Lords; in considering the health clauses of Local Corporation Bills, with reference to compulsory registration of infectious diseases, and in other subjects. The Scientific Grants Committee had not exceeded the grant of £300; but regret was expressed that no satisfactory report had been received from the recipient of a special grant of £100 for research upon methods of conferring immunity in septic diseases. The Scientific Scholarships, held for three years by Mr. Watson Cheyne and Dr. Augustus Waller, would expire in October. Elaborate reports had been received from Mr. Cheyne upon the Relation of Micro-organisms to Disease, and from Dr. Waller upon the Fatigue and Recovery of Muscle and Nerve. The Collective Investigation Committee apply for a renewal of the annual grant of £600; and the Council being aware that many members of the Association feel disappointed with the inadequate results of this movement, have appointed a subcommittee to inquire into it from a financial point of view. The Middleman prize for the best essay on Discoveries in Ophthalmic Science and the Stewart prize for the best work on Contagious Diseases would again be awarded. The question of more commodious premises had been considered by a Committee of Council, but no definite result yet arrived at. A series of rules and regulations regarding the appointment of committees had been adopted by the Council, and were embodied in the report, which concluded with an enumeration of some of the losses sustained by death during the past year.

Sir B. W. FOSTER, in moving the adoption of the report, briefly commented upon the paragraphs of the report. As regards direct representation, he said that this was due to the untiring assiduity of Dr. Waters. The whole status of the profession would depend on those who might be elected. With respect to improved premises for the Association, he contended that it would be unwise to spend all the capital of the Association in securing them; for, as a representative body of the profession, they might some day require funds if they were engaged in contending with great corporations. The future of the medical profession depended on the way in which they developed their resources.

Dr. CARTER (Liverpool) seconded the motion. He referred to Medical Reform and the great assistance given by Sir B. W. Foster in Parliament in securing three representatives for England. He pointed out that the British Medical Association, having been mainly instrumental in securing this favour of Direct Representation, should take steps through its Medical Reform Committee to select three gentlemen who might be supported by the Association and profession at large.

Dr. MORRIS (Spalding) thought the allusion to representation in the Council report was insufficient, seeing the important position taken by the Association amongst general practitioners. The representatives must be general practitioners themselves, for this branch of the profession had been too long ignored. He himself was at the service of the Association. He suggested that lists should be issued by the Council, and members should indicate those whom they preferred, the three names approved by the majority being selected. Unless some such steps were taken the election would be influenced by those already in power.

Mr. NICHOLSON (Hull) suggested that the Council should make the selection, and that the names selected should be suggested by the whole profession.

Mr. HUGH KER (Halesowen) said it was of the greatest importance to have a proper selection of candidates, and he suggested an alternative plan might be a ballot by the members present at the Brighton meeting.

Dr. DEAS (Exeter) questioned the desirability of this subject being introduced in a discussion on the Report of the Council; and Mr. V. JACKSON (Sheffield) thought the subject might be left to the Presidents of the Branches.

Mr. MARSHALL (Dover) asked about the expenditure for contributions to the journal, and suggested that the Association might take up the subject of medical protection, and the prosecution of unqualified practitioners as of greater practical utility than collective investigation.

The Report was then adopted, and Dr. CARTER gave notice of a resolution about the selection of candidates for the Medical Council.

Dr. WARD COUSINS moved an alteration of the bye-laws, so as to admit of the Colonial and Indian Branches being properly represented upon the Council. The matter was referred to the Council.

Mr. JOHN DIX (Hull), after failing to secure the postponement of the subject to the coming meeting, then moved a resolution referring to the Council the subject of the payment of the travelling expenses of the representatives of the branches to the meetings of the Council. The greatest possible sum thus required would not exceed £500, and he thought it was a mere act of justice.

Dr. DEAS seconded the motion, which was opposed by Dr. BRIDGWATER and Dr. EYTON JONES, and lost; but some confusion prevailed owing to the prolongation of the meeting beyond the hour fixed for adjournment.

The adjourned meeting took place in the evening. There was a large attendance. The proceedings commenced by Sir B. W. Foster introducing Dr. Nathan S. Davis, of Chicago, President-elect of the International Medical Congress.

The President (Dr. WITHERS MOORE) then delivered his address. After a few introductory remarks, in the course of which he referred to the meeting of the Association at Brighton thirty-five years ago, and the changes that had taken place, not only in the locality and in the Association since that time, but also in the science of medicine, he alluded to the great prevalence of indiscriminate gratuitous medical relief, and the question of medical fees. He then proceeded to the main topic of his address, which dealt with the higher education of women, meaning by the phrase an education "which aims at raising women (as it imagines) to the masculine level, by fitting them for the exercise of brain-power in competition with man." Is it good, he asked, for the human race that women should be trained and admitted to compete with men in departments from which they have hitherto been excluded by feeling and usage, and by legislation? Is such a competition demanded by the "rights of women," or by "justice to women"; do their duties admit of it? The old chivalrous ideal was different; it held that woman should be protected from the rude battle of life by the work and labour of man, but if this ideal is to be changed, then the age of chivalry and courtesy will pass away. Apart from this sentimental aspect of the question, he held that "it is *not* for the good of the human race, considered as progressive, that women should be freed from the restraints which law and custom have imposed upon them, and should receive an education intended to prepare them for the exercise of brain-power in competition with men;" for such a cause could only incapacitate them for their own proper function which nature has assigned them in the maintenance and progressive development of the human race. It will hinder those who would have been the best mothers from being mothers at all, or, if it does not hinder them, more or less it will spoil them, and no training will enable themselves to do what their sons might have done. He disclaimed any covert intention of proving that women are unfitted for the practice of medicine, for in many walks open to women—as music, literature, and the fine arts—none had been so distinguished as men, and the day is far distant when a Hippocrates, a Harvey, a Haller, or a Hunter will adorn the ranks of the lady doctors. As Herbert Spencer says, "The first requisite to success in life is to be a good animal; and to be a nation of good animals is the first condition to national prosperity;" and Dr. Moore contrasted the haphazard way in which in the case of the human animal conjugal union was arrived at, as contrasted with the care bestowed on such unions by the breeders of the inferior animals. Since, however, there can be no interference with individuals, there should be no attempts made whereby the fittest mothers should be shut out from motherhood. To encourage competition with man in the intellectual pursuits was to make vast demands on the vital powers, and *pro tanto* interfere with maternity and its duties. Education is very expensive, physiologically as well as pecuniarily, and growing girls are not physiologically rich enough to bear the expense of being trained for motherhood, and also that of being trained for competition with men in the severer exercises of the intellect. Again, the first ten years of life was the most important period of a man's existence, and how important it was that the mother should be fitted for the charge and training of her offspring at this period. Still

more wonderful than the change undergone by the new-born infant and the child of ten years were the changes that go to build up the organism in the period of gestation. All the tissues and organs are developed from the maternal substance. "Manifestly it is before his birth, mainly, that the man is made. From and after his birth he has mostly not to be made, but to grow; the making of him has been begun and carried on, and well-nigh completed in his mother's womb." How important then that she should be in such a vital state as to fit her for discharging duly the arduous functions of maternity. The detrimental influence of mental labour, in producing infertility and in damaging the physique of women, was illustrated by a statement of Herbert Spencer, and Dr. Matthews Duncan's opinion was cited that "amenorrhœa and chlorosis, and development of great nervousness, are frequent results of over-pressure in education at or near the important epoch—fifteen to twenty years of age. To the same cause I have often attributed destruction of sensuality of a proper commendable kind, and its consequent personal and social evils." The opinions of Sir B. Brodie, of Dr. E. H. Clarke, of Boston, of Drs. Emmett, Goodall and Lownes, and Mr. Lawson Tait, all express the same view. Dr. Moore, after alluding to other arguments in support of his contention, concluded as follows:—"But time admonishes me to make an end. My argument may be summed up very simply. Excessive work, especially in youth, is ruinous to health, both of mind and body; excessive brain-work more surely so than any other. From the eagerness of woman's nature competitive brain-work among gifted girls can hardly but be excessive, especially if the competition be against the superior brain-weight and brain-strength of man. The resulting ruin can be averted—if it be averted at all—only by drawing so largely upon the woman's whole capital stock of vital force and energy as to leave a remainder quite inadequate for maternity. The Laureate's 'sweet girl-graduate in her golden hair' will not have in her the fulfilment of his later aspiration—viz.,

> 'May we see, as ages run,
> The mother featured in the son.'

In the prophet's words, 'She will not have strength to bring forth'; her reproductive system will more or less have been atrophied; she will have lost her womanhood's proper power. With the power, she will have largely lost also the inclination; of 'Love's sweet want,' as Shelley calls it, she will know little, for, in Dr. Duncan's more matter-of-fact language, she will have lost 'sensuality of a proper commendable kind.' Unsexed it might be wrong to call her, but she will be more or less sexless. And the human race will have lost those who should have been her sons. Bacon, for want of a mother, will not be born. She who should have been his mother will perhaps be a very distinguished collegian. That one truism says it all—women are made and meant to be, not men, but mothers of men. A noble mother, a noble wife—are not these the designations in which we find the highest ideal of noble womanhood? Woman was formed to be man's helpmeet, not his rival; heart, not head; sustainer, not leader. Many times, indeed, woman's fate has set her in the foremost place; in some of those times, no doubt, such place has been well and grandly filled by her. Yet even then our admiration is not untinged with compassion. Even in this year of approaching or commencing jubilee, it is not so with us when we think of that Crown, Royal and Imperial, which, splendid as it is, has so long been left 'a lonely splendour'? 'Victoria Regina et Imperatrix'—bravely, proudly, gloriously is the burden borne; but would she, who knows its weight, wish a like weight to be laid upon any daughter? Let this address come back to the humbler life which more belongs to it. 'I am king of the household, and thou art its queen,' says the happy husband in Longfellow. Permit me to conclude to-day with King Solomon's eulogy for the happy home-queen, the happy wife. 'Who can find a virtuous woman? for her price is far above rubies. The heart of her husband doth safely trust in her; she will do him good and not evil all the days of her life. She rises while it is yet night, and giveth meat to her household, and a portion to her maidens. She girdeth her loins with strength, and strengtheneth her arms. She perceiveth that her merchandise is good, her candle goeth not out by night. She layeth her hand to the spindle, and her hands hold the distaff. She stretcheth forth her hands to the poor, yea, she reacheth forth her hands to the needy. Her husband is known in the gates, when he sitteth among the elders of the land. Strength and honour are her clothing, and she shall rejoice in time to come. She openeth her mouth with wisdom, and in her tongue is the law of kindness. She looketh well to the ways of her household, and eateth not the bread of idleness. Her children arise and call her blessed; her husband also, and he praiseth her. Favour is deceitful, and beauty is vain; but a woman that feareth the Lord, she shall be praised.'"

Dr. N. G. DAVIS (Chicago), in proposing a vote of thanks to the President for his able and interesting address, said that he cordially sympathised with its sentiments. There could be no room for doubt as to the truth of the statement it contained, and in America they had abundant evidence of it; when the laws of nature are set at defiance a fatal blow is struck against the welfare of the race.

The vote was carried by acclamation and acknowledged by Dr. Moore.

A motion by Mr. J. Marshall (Dover) respecting the publication of notices of births, marriages, and deaths in the journal—free of charge to members—was after a brief discussion referred, on the motion of Mr. Wheelhouse, to the Council.

The Second General Meeting was held on Wednesday morning, August 10th, Dr. Withers Moore, President, in the chair. The large hall was very nearly filled by the audience.

Sir B. WALTER FOSTER, President of Council, announced that although invitations had been received from Glasgow and Leeds for the meetings of the association in 1888 and 1889, yet no invitation had been received for next year. He therefore moved that the Council be requested to make arrangements for the annual meeting in 1887, and empowered to nominate a President-elect.

A number of foreign delegates were then introduced to the President, and received with applause.

The PRESIDENT alluded in suitable terms to the death of Dr. Austin Flint, who had cordially accepted the invitation to deliver the address in medicine at this meeting, and had prepared that address, which had since been published. The Council of the Association had invited Dr. Billings to take the place thus vacated.

Dr. Billings then delivered the address on medicine. (See p. 283.)

A vote of thanks to Dr. Billings for his address was proposed by Sir J. Crawford, Director General, seconded by Dr. Ord, and carried with great enthusiasm.

The list of Members of Council was read by the Secretary.

Sir B. W. FOSTER then announced that a prize of £20 had been awarded to Dr. Ward Cousins for the invention of a sound-deadener, and related the circumstances attending that award.

Dr. WARD COUSINS, in gratefully accepting the honour, announced that he would offer a prize of £20 for a subject which would be duly announced.

DIRECT REPRESENTATION OF THE PROFESSION.

Dr. CARTER (Liverpool) moved: "That it be an instruction from this meeting to the Council of the British Medical Association to select three names of gentlemen suitable for election to the General Medical Council by the medical practitioners of England, and to submit them to a future general meeting during the session of the Association in Brighton." He justified this course on the grounds that the time for selection was short; that to procure capable representatives it is necessary to have some organisation; and they could have no fear of leaving the selection to so representative a body as the Council of the Association.

Dr. EYTON JONES seconded the motion, the object being that general practitioners should be represented; and he suggested as one of the representatives the name of Dr. Waters.

Dr. HUGH KER supported the motion, but suggested that more names be proposed than required, and that the Irish and Scotch branches should take the matter up themselves.

Dr. DOLAN (Halifax) proposed as an amendment that it was inexpedient that the Association should interfere with the election, and that its action should be limited to affording facilities for the circulation of the names of candidates, with a view to get the opinion of members of the Association upon them. Dr. Carter's motion would, he said, place in the hands of a caucus the franchise for which they had so long struggled. He reminded them that the Association was not the only power that had moved to secure them

this right. THE LANCET had been working for years. Were they going to hand this selection to a body which might lead to the exclusion of so good a candidate as Dr. Glover? The question had been sprung upon the meeting. They must have general practitioners for their representatives, and not consultants, who are already amply represented.

Dr. MORRIS (Spalding) suggested that the selection could be made through the medium of the journal.

Dr. DUNCAN (Glasgow) objected to the Scotch and Irish representatives being disregarded.

Mr. G. BROWN (London) said the Association did not represent the profession, and insisted that candidates should come forward on their own merits, and not as nominees of any body.

Dr. ALDERSON thought that the machinery of the Association might be used for the election, but objected to placing the selection in the hands of the Council. He did not think a candidate should be excluded just because he was not a general practitioner.

Dr. CARTER explained that he had proposed to place the matter in the hands of the Council, because he felt it could be thoroughly trusted. But in obedience to the evident sense of the meeting, he withdrew his motion.

Dr. DOLAN'S amendment now being a substantive motion, was put to the meeting.

Dr. BERNARD O'CONNOR was engaged in speaking against the motion, when it was withdrawn by Dr. Dolan, and the meeting concluded with the result that no action will be taken at all in the matter.

In the afternoon a garden party was given by Sir Julian Goldsmid at St. Ann's Wells; and in the evening a brilliant conversazione was given at the Royal Pavilion by the President of the Association and the members of the South-Eastern Branch.

At the third general meeting on Thursday morning thanks to Mr. Humphry for his address in surgery were moved by Sir W. Mac Cormac, and seconded by Mr. Wheelhouse, and carried *nem. con.* Sir B. W. Foster then addressed the meeting in declaring the award of the Association Gold Medal to Dr. E. Waters for his long-continued and devoted labours in the cause of Medical Reform. The medal was founded in 1870, and has been awarded three times before, to Dr. Davies of Swansea, to Surgeon-Major Reynolds, and to the late Dr. Farr respectively. The President then presented the medal, and Dr. Waters acknowledged the award, which he said was a distinction which, of all others, he could most have desired. The Stewart prize was awarded to Dr. Robert Cory, for his self-denying research in vaccination, and the Middlemere prize was divided between Mr. G. Berry and Mr. Adams Frost. A delegation from the American Medical Association, including Drs. N. Davis, Brodie, Pancoast, Sinclair, and others, attended, and Dr. Davis, President-elect of the International Congress, gave a warm invitation to the profession of this country to attend the meeting at Washington in September, 1887. The delegates were most heartily received.

THE SECTIONS.

MEDICINE.

The first meeting of this Section was held in the Music-room of the Royal Pavilion on Wednesday afternoon. Dr. Broadbent, President of the Section, occupied the chair. The following subject had been selected for special discussion:—"Cases in which disease of the valves of the heart has been known to exist for upwards of five years without causing serious symptoms." Introduced by Sir ANDREW CLARK. From notes of cases coming under observation during the last fifteen years he brought forward certain points for discussion. He excluded from his tables all murmurs heard in the pulmonary area, all murmurs which were presumably variable, and what he called murmurishness. The cases had thus been repeatedly sifted. He noted 684 cases of valvular disease without symptoms showing how many persons must be going about with heart disease, and yet not suffering from it. There were also a large number of patients who suffer so slightly that they never consult a doctor, and thus the murmurs are perhaps never detected. Of the 684 cases the great proportion of 272 consulted him for indigestion, 57 on account of some rheumatic condition, 22 for gout, 44 for nervous ailments, 17 for eczema, and only 4 for phthisis. Lesions of the heart produced in youth were noticed to be greatly recovered from if development were not complete. He considered the Collective Investigation Committee were quite justified in taking up this subject, because town physicians do not know sufficient of the family and personal histories of these patients. It was the general practitioners who could supply the necessary information. He thought the Committee might take up those cases in which, though symptoms are experienced, the patient continues even to advanced life in a comfortable way. He described cases in which the valvular lesion was known to have disappeared. He drew impressions from these cases with reference to what favoured and what impaired recovery. He considered that impressions grew up with all of us into a clinical instinct, which, for the most part, served us well. Those who were exempted from the secondary effects of heart disease were those who placed themselves in favourable physiological conditions, especially with regard to the health of the mind, an absence of worry and disquiet. As disfavouring recovery, all disobedience to physiological laws, irregularities of living, especially eating and drinking. Many patients are over-fed by their anxious friends, and he considered that the abuse of tea, and especially of tobacco, weakened the ventricle. The failing strength of the ventricle was to be feared more than anything else. He concluded by referring to many cases which were proved to exist with valve lesions, and yet without symptoms, even to the extreme of life; others who have symptoms and yet live to advanced age: others, again, whose heart murmurs disappear. He considered that if this investigation were pursued carefully, it will do more than any other for the completion of the natural history of these diseases, and will render most important services to mankind.

Dr. GAIRDNER continued the discussion, and observed that his own impressions agreed very much with those Sir A. Clark had expressed. He referred to this subject in print twenty-five years ago, and said then, that there was a tendency to overrate the importance of murmurs, to pay too much attention to sound rather than the circumstances, and to take too serious a view of cardiac murmurs and disease generally. He recorded nine cases illustrating the more favourable prospects than usually admitted in this class of cases.

Dr. CLIFFORD ALLBUTT laid stress upon whether the cause of the valve disease was intrinsic or extrinsic. He considered dietetic considerations very important, and alluded to the great weakening effect of alcohol upon the muscle of the heart. He thought that with alcohol the mischief was essential; with tea and coffee, the effect being produced through the nervous system, was readily recovered from. He believed that a noisy murmur was not often a serious one, and that the important point was whether any alteration occurred in the current of blood. He drew attention to the danger of sudden death always existing with aortic regurgitation, whereas the occurrence of acute dilatation with mitral disease was recovered from. He concluded by observing that this discussion ought to comfort physicians who were outliving the pathological era in which they were first trained, and which placed too much importance upon organic changes.

Dr. BRISTOWE did not doubt that occasionally organic murmurs do disappear. He recorded a case in which heart disease existed for forty-five years, and others of aortic obstruction which had existed a long time in fair health. The loudness of a murmur was not a criterion of its seriousness. He thought doctors often discovered heart disease when the patient knew nothing previously about it, and made them miserable. He referred to Murchison having died in harness, and said he would often recommend others to run the risk also.

Dr. LEACH, in referring to the treatment in these cases, asked whether we should advise patients to do nothing and keep quiet, because they have no murmur; or go to the other extreme, with some German authors, and advise mountain climbing and severe exercise. He thought it was not wise to consider a man with heart disease as equally favourable for insurance as one without.

Dr. BOWLES considered that for collective investigation purposes we must not disregard temporary murmurs. They have had an important meaning. We were, perhaps, apt to attach too much importance to them in our prognosis.

In summing up, Sir ANDREW CLARK said, that in considering a case for life assurance he weighed these facts—the time the mitral disease must have existed; whether independently of disease of the heart-walls; whether in

existence for over two years; whether associated with attacks of negative congestion; whether the general health was good, and whether there was a fair radial pulse. Murmurs must be considered in their relation to the general health, and the condition of the heart-wall.

A vote of thanks was passed to Sir A. Clark for opening this discussion.

SURGERY.

Mr. ERICHSEN, President, in opening the section, spoke on the tendency of modern surgery—i.e., the lines that it will be most profitable to follow in the immediate future by those who seek to advance surgery beyond its present limits of undoubted excellence. Will, he asked, these lines be the same as those along which the present generation of surgeons has successfully carried it to so high a pitch of excellence, or will the very success that has attended their efforts in these directions compel a new departure? Have we, in fact, reached the final terminations of the old routes, and must we follow, if not new, at least less well-explored tracks if we wish to reach a uniformly higher level? "Before answering these questions, let us consider the direction in which surgery has advanced since the introduction of anæsthetics, from which epoch I would roughly date the development of what is now known as 'modern surgery.' And here I speak only of surgery proper, not of those questions in diagnosis and pathology which are common to it with the other departments of medicine. This advance has been in three distinct lines. First, and mainly, in the extension of the scope, and in the improvement of the methods of operative surgery. Secondly, in the precision both as to exactitude of performance and certainty in the result of operations. Thirdly, in the application of those methods of scientific research by which those sciences are advanced on which practical surgery is based. The extension of operative surgery since the introduction of anæsthetics is certainly one of the most remarkable phenomena even of this mechanical age. It cannot have fallen to the lot of many of you to have been personally engaged in surgical operations in the pre-anæsthetic period, but to those who, like myself, were then well acquainted with the operating theatres and the wards of the London and of some of the Continental hospitals, and who can carry our minds back to what we should now call the horrors, both as regards physical suffering and total absence of hygienic precautions, of those days, the change that has come over the whole field of operative surgery is more than startling. That the final limits of surgery have been reached in the direction of all that is manipulative and mechanical there can, I venture to think, be little doubt. Within these limits there may be much of movement, of change, of modification in the 'technique,' if I may borrow that word from art; but movement is not necessarily advance, it is often the mere restlessness engendered by dissatisfaction with established methods; change may be the outcome of mere personal vanity, or of more unworthy motives..... But another great advance that has been made in modern surgery is in its precision. Now, there are two kinds of precision, there is the precision which consists in exactitude of performance and the precision which consists in certainty of result. So far as exactitude of performance is concerned, there is little left to be desired in modern surgery. The rules laid down for most operations are so precise that the surgeon can hardly err, the more so as the use of anæsthetics by rendering the patient insensible to all suffering makes it unnecessary to operate against time, a cause of much fatality in former days, and the use of Esmarch's bandage renders the limb as bloodless as if it were in the dissecting room. Almost absolute precision of result has also been obtained, so far at least as the wound is concerned by the employment of strict hygienic precautions and the adoption of the antiseptic method in one or other of its various modifications. Precision of result, so far as recovery is concerned, is less certain; but here also the gain has been immense, and so great has the advance been, that instead of looking upon any given operator as having a definite rate of mortality, often high, we now look upon death after operation, and as the direct result of the operation, as a rare contingency, and one to be carefully inquired into..... The development of those methods of scientific research by which those sciences are advanced on which the practice of surgery is based is the next point to be considered, and here we come to ground that has been less assiduously cultivated than other fields of surgery, but which certainly may be expected to yield a fruitful and abundant harvest in the future. It may, in truth, be doubted whether there is really a 'science of surgery' in the sense that we attach to the word 'science' when applied to other departments of human knowledge, the observation of natural phenomena, collections of facts governed by and subordinated to certain fixed laws. We should be more correct in saying that surgery is based on certain of the natural sciences, such as those of biology, anatomy, physics, and chemistry, and on pathology. The art of surgery has been in no way dependent for its advance in the past on the cultivation or the progress of science. There was a highly advanced empirical art of surgery long before the natural sciences existed as such. The art has ever been in advance of the science, and the science has too often had to content itself with giving a rational explanation of the phenomena already determined by the art of surgery..... Art is final, but science is illimitable. We have reached finality in the mere mechanical art of surgery, both as to expansion of its limits and the precision of its practice. But we are yet on the very threshold of the science of surgery. We have yet to learn much from that compound science biology, in its application to the elucidation of surgical problems, that compound science of modern creation into which physiology and histology, pathology, chemistry and physics, enter in equal proportions, which works by means of experimental research, and I venture to think that this is the line of investigation which promises the greatest and most useful results in the cultivator of surgery in the immediate future. The old lines also of ordinary clinical observation and of dead-house pathology have long since been followed to their final termination; we can but multiply the facts already so carefully observed, and so admirably recorded by countless observers in every civilised country. It is not by following these old lines that modern surgery will owe its advance, but it is in the application to it of those means of experimental research which are now being worked out in the biological and pathological laboratory that we may hope to find the solution of many of those problems that have hitherto baffled the surgeon."

Sir HENRY THOMPSON then opened the discussion on Supra-pubic Lithotomy. Being strictly limited, he said, he would condense his remarks as much as possible, and limit himself to the discussion of the best manner of removing large stones in adults. Formerly it was a choice between lateral or median lithotomy, with a few cases for lithotrity. Now, the latter operation was universally selected for nine out of every ten cases, and it was a question how the remaining case should be dealt with. Lateral lithotomy seemed a simple and an expeditious operation for a looker-on, but for those who had access to the wards it was a fatal operation as formerly practised. In the earlier part of his career he had tested the several methods, and the contrast between any method of lithotomy and of lithotrity was very striking. In removing a large mulberry calculus through the perineum more severe must be the injury to the neck of the bladder and to the prostate. Cheselden had had remarkable success for small and medium-sized stones in children, and this was probably the best operation he could have done, seeing that crushing had not then been invented. But to-day the situation was completely changed. The supra-pubic operation was well adapted for medium-sized and for large stones, because the space is practically unlimited; because there was no danger of hæmorrhage, or, if it occurred, it was easily dealt with; because the incision was easy to make and quite safe; because the after-treatment was easy, and the use of antiseptics possible; and finally, because neither rectum nor sexual organs were in any way interfered with. It had, however, been argued that there were some dangers, notably two—the peritoneal cavity might be opened, or there might be extravasation of urine into the surrounding cellular tissue. Dealing first with the latter, Sir Henry pointed out that this could hardly occur if the rules of procedure were at all carefully carried out. It was conceivable that extravasation might occur if the tissues were much disturbed. This would be likely to follow if the bladder, not being properly supported, should tend to recede back into the pelvis as its contents flowed out after it had been incised; hence the importance of carefully fixing it before the incisions were made into it. Then, as regarded the peritoneum, this danger need not occur. Garson's experiments, amply confirmed by Petersen and others, showed the value of rectal distension; and, besides, the floor of the bladder could be seen when it was

well raised out of the pelvis by a distended rectum, and this was a great advantage, especially when operating for tumour of the bladder. Sir Henry next described the details of the operation (now very generally known through his *brochure* on this subject). He thought there was no advantage in suturing the bladder; it was better to leave it open in order to effect drainage, which a catheter in the urethra failed to accomplish.

MR. REGINALD HARRISON (Liverpool), for Dr. Morrison, showed a large uric acid calculus (the largest on record) which had been removed by this method: a pair of midwifery forceps had been used for its extraction. For himself, he spoke with reserve on this supra-pubic operation; he had operated on about fifty children by the left lateral method without losing a single one, and he should hesitate about changing his practice until circumstances convinced him that he could improve on his present results. To judge from the recorded experience of others, lateral lithotomy had proved a difficult operation, and for such men the easier one would doubtless be welcomed. For stone cases, however, attended with complications, such as sacculation or cystitis, he felt sure that the perineal method would prove the better and the more satisfactory.

MR. CADGE (Norwich) would prefer to take a midway course between Sir Henry Thompson, who went for the operation, and Mr. Harrison, who condemned it. Perhaps on account of his old associations and prejudices, he (Mr. Cadge) was apt to see difficulties where others saw none; perhaps, too, he was reluctant to let the older operation lose the place of honour it had so long occupied. Nor could he forget that Cheselden had abandoned it, and never returned to it. But at present it was impossible to lay down any principles on which it could rest; the aggregate experience of all surgeons hardly amounted to 100 or 150 cases. As regarded the wound, he was rather in favour of leaving it open; at most, perhaps, one or two stitches, for the sake of securing coaptation, might be desirable. He then referred to cases quite unsuited for the supra-pubic operation—cases of contracted bladder. He would advise that surgeons keep their minds open, carefully experimenting on the dead, and cautiously practising the operation in suitable cases on the living.

MR. JESSOP (Leeds) related an interesting case, in which he had quite failed to grasp the stone with the lithotrite, but quickly extracted it by the supra-pubic method. He was much disappointed with Sir Henry Thompson's opening paper. It contained nothing new, nothing that had not already been published at least twice before. He had been hoping to learn the cases in which Sir Henry would advise this operation before any others. How would he or Mr. Cadge deal with a moderate-sized stone in persons with enlarged prostate? Then, as regards children: he confessed that in a small child lateral lithotomy was a difficult operation; on the other hand, the bladder in children lent itself readily to the supra-pubic method.

MR. BARWELL spoke in favour of the operation, both for boys and girls.

DR. WARD COUSINS (Plymouth) seemed perfectly satisfied with the old-fashioned lateral lithotomy for small and median stones. With improved tools, lithotrity bade fair to take its place. Nevertheless, supra-pubic lithotomy was a very easy operation.

Surgeon-Major KEEGAN (India) showed a remarkable series of stones removed from children by crushing and rapid evacuation. There were 58 consecutive cases, with only one unsuccessful result. Some of the stones were very large indeed. The average stay in hospital amounted to 77 days. He therefore advocated this operation in preference to any other, unless specially contraindicated for stones of a certain size. The question was, where should the supra-pubic method come in? He thought for all stones weighing about 4 oz. and upwards. As a proof of the success of lateral lithotomy, he referred to the published results—143 consecutive cases—of his friend Dr. Freer, without a single death.

Sir WM. MAC CORMAC related a case in point, with primary union of the incisions.

MR. JACOBSON related three recently operated cases, and advocated the operation for its own sake. He referred to the frequency of relapse after lithotrity; once in seven or eight cases (Cadge), as compared with one in fifty cases after lithotomy. There were the relapses of the leading operators; in less skilled hands they would probably be more numerous. Hence this was a strong argument in favour of the easier method. This, the supra-pubic operation, was evidently the operation for country surgeons, where want of opportunity lost them something of the facility which more experienced surgeons were constantly acquiring. He had not used sutures, and rather inclined not to do so. He should very much like to know something of the personal after-history of those who had been cut for stone while young. What were the real facts as regards the emasculation which was asserted to follow in a proportion of the cases?

MR. BRUCE CLARKE made some observations on the use of the rectal bag. In a case at which he had assisted no inflation was necessary; the size of the stone sufficiently raised and distended the bladder.

DR. HINGSTON (Montreal), as a pupil of Civiale, felt that lithotrity ought in adults always to take the place of lithotomy when practicable. In children lateral lithotomy is so simple, so easy, that he failed to see why anyone should desire to adopt new procedures. He recommended that the size of a stone should be indicated rather than its weight, as the latter could only be ascertained after its removal. For stones three ounces and over he would be inclined to try the supra-pubic method.

OBSTETRIC MEDICINE.

The President, DR. ALFRED MEADOWS, F.R.C.P., on taking the chair delivered an address. In his opening remarks he offered, in the name of the Association, a welcome to all, and referred especially to those whom, though foreigners in a national sense, we are proud to regard as brothers, whose lives are spent in and whose hearts are devoted to the study of obstetrics and gynæcology. Reference was next made to the growing differentiation on the subjects of which this Section has cognisance. More and more evident each year is the divergence which is springing up between obstetrics and gynæcology, and the opinion was strongly advanced that in future there should be two sections for their consideration, and if that were so it would be to the advantage of both; certainly to gynæcology. Many gynæcologists are not obstetricians. Neither are many practitioners of the obstetric art gynæcologists. The advances which have been made and the brilliant achievements which have been wrought in the practice of gynæcology during recent years have placed this department in the foremost rank of surgical art, and if we look up and down the history of surgery during the last quarter of a century it would puzzle anyone to find a parallel to the chapter which may have been written of the abdominal surgery introduced by the gynæcologist. "Nowhere is there such a record of life saved, of suffering averted, of health restored, of happiness secured, as is inscribed on that tablet of time which the knife of the gynæcologist has carved in letters of indelible characters." Allusion was made to the subject to be introduced by Dr. Barnes, "The Alternatives to Craniotomy," as likely to mark an epoch in this country, and will lead to a new departure by which many lives will be spared, and the conscience of the obstetrician will in the future be made happy by the promulgation of a new law which will save his hand from becoming an instrument of slaughter; for the resources of civilisation cannot be exhausted until some means are found out by which in every case of labour we may with reasonable chances of maternal safety extract a living and viable child from the mother. Porro's operation has undoubtedly advanced abdominal surgery, and is a great improvement upon Cæsarean section, and it has this merit, that it insures the mother against a repetition of the peril in which pregnancy places her. A subject not less inferior is the one frequently spoken of as "The Removal of the Uterine Appendages," but if this term is the best that can be selected it expresses a physiological error, for the ovaries and the Fallopian tubes ought not certainly to be regarded merely as appendages to the uterus, but rather that the uterus is an appendage to the other organs, which are undoubtedly its superior in physiological work. One point, however, is clear, that their removal is becoming—if it has not already become—one of the most startling innovations in modern surgery, and it is likely to occupy professional attention for many years. Dr. Meadows thoroughly believes in the sound and scientific basis upon which the operation is founded, and that it is a valuable addition to our methods of curing certain cases of ovarian and tubal disease which are beyond the reach of therapeutic remedies. And he en-

dorses the view of its applicability to certain forms of nervous diseases which have hereto resisted all attempts of cure by means of drugs, even when these so-called appendages are the seat of any cognisable disease, and lastly, by this operation, the sufferings caused by the presence of certain forms of uterine fibromata may be entirely removed, the growth of the tumour be thereby arrested, and its disappearance in some cases effected. Again, in women who are the subjects of such pelvic distortion that the birth of a living child *per vias naturales* is an impossibility, it may be a question whether the removal of the ovaries and Fallopian tubes ought not to be undertaken. In a final allusion to this operation a word of caution was uttered lest the facility with which it can be performed should tempt practitioners to be too lavish in the selection of the cases alleged to be fitting; greater perfection in diagnosis was also required, and it was possible to lose sight of the fact that there is such a thing as medical treatment, both topical and general, and that *not* every case of disease of this appendage must necessarily come under the radical treatment of the knife.

Dr. BARNES read a paper on the Alternatives of Craniotomy. He said: "I will submit the following summary of the arguments set forth:—1. The legitimate aspiration and the tendency of science is to eliminate craniotomy on the living and viable child from obstetric practice. 2. The advance of hygienic rule, the improvements, the forceps, in turning, in the induction of labour, and in obstetrics generally, have materially curtailed the field within which craniotomy can be justifiably applied. The extension of the axis-traction curve to the forceps will, I believe, still further curtail the resort to craniotomy. 3. In the most extreme degrees of pelvic distortion, where delivery *per vias naturales* can only be effected by the best appliances and the highest skill, and with appreciable risk to the mother, Porro's operation is the legitimate alternative, for craniotomy, if the opportunity of inducing abortion be gone by. 4. In less advanced degrees of pelvic contraction, but still incomparable with the delivery of a living child *per vias naturales*, the opportunity of inducing abortion having gone by, the Cæsarean section may be a legitimate alternative of craniotomy. This is the most debateable point. 5. In the minor degrees of contraction, say from 3 in. to 3½ in., the opportunity for inducing premature labour having gone by, the far greater safety to the mother obtained by craniotomy makes this the proper course to adopt—at least, until it can be shown that the Cæsarean section is so improved as to be equally safe to the mother. The mother's right to be rescued stands before that of the child. 6. In other emergencies than deformity, as in obstructed labour from ovarian tumours, the alternative to craniotomy, if possible, is to remove the tumour. 7. In cases of immovable tumours, Porro's operation is the proper alternative. 8. In ruptures of the uterus, the child being delivered or not, Porro's operation is the proper alternative. The interests of mother and child coincide. 9. In cases of disease or tumours of the uterus, Porro's operation will generally be the proper alternative. 10. In atresia of the cervix or vagina craniotomy or Cæsarean section may be necessary, but incisions and dilatation may more frequently be the proper alternative. 11. When obstruction is due to hydrocephalus, or dropsy in the child embryotomy or tapping is indicated. 12. When the child is dead embryotomy is indicated, and decollation when turning is hazardous from impactions of the child. 13. In convulsions and hæmorrhages the proper alternatives for craniotomy are found in the more scientific methods of concluding labours under these complications. Lastly. But the dream of Tyler Smith, the abolition of craniotomy, will be fully realised only when hygiene shall have triumphed over disease and deformity.

PUBLIC MEDICINE.

At the opening of this Section Dr. R. P. B. TAAFFE, President, selected two or three points for discussion, the first being Smoke Abatement and Purification of Gas. He urged the necessity for a strong effort being made to reduce the amount of smoke which was daily given off in every town, and he suggested that every occupier of a house should be required to exchange at least one old-fashioned stove for a smoke-consuming stove in every year. He next described Mr. W. J. Cooper's method for purifying gas, and he expressed the hope that this process, which is being successfully employed at Tunbridge Wells, will be made compulsory in all gas-works by the Legislature. The decrease in the death-rate during the decade 1871-80 was next touched upon, and it was pointed out that this rate, amounting to 21·7, was lower than in any preceding decennium since civil registration began. During the current decade the average death-rate is still lower, being only 19·3, a result which, as Dr. Ogle says, is due to the effects of the ever-increasing efforts to improve the sanitary condition of the country. The results of this decrease, as affecting prolongation of life, was then discussed, and it was shown that this amounted for every male to an increase of more than two years. The death-rates of the borough of Brighton have declined 2·7 per 1000 since 1851-60, and those of Kemp Town, Preston, and Hove were during 1885 as low as 14·1, 12·9, and 12·5 per 1000. The lecturer then proceeded to show the extent to which the public misunderstood the death-rates in the weekly returns of the Registrar-General—mistakes which were shared in by Doctors of Divinity and a Fellow of the Royal Society; and he pointed out with much exactness the meaning of the Registrar-General. Infantile diarrhœa, which was next commented upon, was attributed mainly to improper feeding and improper nursing, and he expressed the opinion that even infants at the breast may be improperly fed by a too frequent supply. Diarrhœa amongst the children of the poor is much more common and fatal than among the children of the rich, and this is due to the larger number of poor children who are brought up by hand, the uncleanly condition of feeding-bottles, and the difficulty of obtaining medical advice. Dr. Taaffe considered the mortality from autumnal diarrhœa occurred as the result of the stomach and bowels being in a state of subacute congestion for months previously, that the climatic and other epidemic influences at this period act secondarily in determining the disease. After a brief reference to Mr. Power's investigations into the outbreak of scarlet fever in connexion with milk from Hendon, Dr. Taaffe gave some account of recent legislation, and spoke of the rapid growth with which the education of the public on sanitary matters had progressed, indicating the directions in which the law should be amended, and finally urged the improvement of London government on such a basis that example might be set to the rest of the kingdom.

PATHOLOGY.

The PRESIDENT (Julius Dreschfeld, M.D.) delivered an opening address on the Relations of Pathology to the other branches of Medical Science, and on the Study of Pathology in England compared with other countries. Of the subdivisions of the subject, the anatomical, physiological, and etiological, the first named and oldest has received the largest share of attention. It may be said to have been founded by John Hunter, who bequeathed to England a museum superior to any in Europe, and which, thanks to the labours of Sir James Paget and his able fellow-workers, has been richly supplemented and kept pace with the advancement of pathological science. The advances in histology had their application in pathology—e.g., the discovery of karykinesis and the reaction of cells and tissues to special colouring agents, as developed by Ehrlich. Pathological anatomy also enables us to trace the steps of diseased processes, and how to arrive at their cause; and the history of tuberculosis shows how this may anticipate the discoveries of experimental science. This latter line of research—pathological physiology, the importance of which was recognised by Hunter,—is hampered in this country. It receives much support from experimental physiology, and in pathology experiment is even more needed than in physiology—as in the study of inflammation, thrombosis, and fever,—and the whole field of bacterial pathology. Dr. Dreschfeld showed how the legislative restrictions in this country placed experiment on the action of poisons under great difficulties, and he illustrated this by the loss of an opportunity to verify Pasteur's assertions on hydrophobia in a case recently in the Manchester Infirmary. The patient died two days after admission, and there was consequently no time to apply for the necessary licence to perform the inoculation experiment with the fresh medulla. He urged that in the interests of humanity, as well as of medical science, these anti-vivisection restrictions should be relaxed, and thought a fresh appeal might not be altogether fruitless. But pathology also gains much support from clinical medicine—witness the pathology of nervous diseases, which has made such enormous progress

in the last ten or fifteen years, owing largely to M. Charcot. And not only pathology, but physiology, has gained by these observations. The pathology of Bright's disease can only be elucidated by continued clinical and anatomical investigation; and there are many affections—notably increased arterial tension, digestive disorders, hysteria, &c.—where clinical observation is the chief means of research. Pathology thus covers a large field, too large for one man to devote himself to all parts of it, although much of our pathological knowledge has been due to clinicians; and, conversely, most of the excellent clinicians of England have spent their earlier years in pathological work and pathological research. We require well-endowed chairs of pathology in all teaching centres, and a separate recognition of the subject by examining bodies. It would better prepare the student for his clinical work, and be of the greatest advantage to him afterwards in the exercise of his practice.

A discussion upon Peripheral Neuritis was opened by Dr. Ross (Manchester), who restricted the subject to that of progressive multiple neuritis, the chararteristic of which is its resemblance to diseases produced by poisons circulating in the blood. These toxic causes he summarised in the following groups:—1. Lead, arsenic, copper, &c. 2. Alcohol, bisulphide and oxide of carbon, and perhaps the pains due to prolonged excess of chloroform and chloral, and advanced diabetes. 3. Animal poison, diphtheritic paralysis, syphilis (Buzzard), and many specific fevers; leprosy, and perhaps pemphigus and herpes; very probably also rheumatism and rheumatoid arthritis. 4. A certain number of cases appear to be idiopathic. He described the various symptoms—motor, sensory, trophic. The motor paralysis is of the ordinary atrophic variety; reflexes variable. The extensors chiefly affected—e.g., lead palsy. In alcoholic paralysis there is first double ankle-drop, then double wrist-drop, &c. Ocular paralyses occur in diphtheria and in alcoholism. The diagnosis had to be made from cerebral disease. No doubt several cases of so-called acute ascending paralysis were really of this class; and the distinction can be made by noting that when the hands are involved the muscles supplied by the first dorsal nerve will (unlike spinal paralysis) be attacked after those of the cervical nerves. Death takes place by respiratory paralysis. The gait is quite characteristic, with pointed depressed toe and semiflexed knee.

Dr. BUZZARD followed. He described the histological changes of the neuritis, changes which embraced degenerative as well as inflammatory processes, and exhibited specimens. The limitation to periphery of so many nerves is startling, and suggests some unrecognised lesions in the centre. Duchenne suggested functional disorder of the cord, and the same idea has been further advanced by De Watteville and Erb—that the nerve cells are deranged. But if functional activity of the cord were long suspended the paralysis should be more widespread. Dr. Buzzard suggested that the nerves may be affected through bloodvessels supplying them through irritation of vaso-motor centres. The phenomena of Reynaud's disease are attributed by Peters and Vaillard to peripheral neuritis, but Dr. Buzzard regarded the neuritis as secondary to the altered state of the bloodvessels due to poison acting on the vaso-motor centre. The explanation should be wide enough to embrace the peripheral lesions which arise in chronic diseases of the spinal cord—e.g., tabes. Dr. Buzzard related some cases, and referred to diphtheria, beri-beri, and other diseases, due apparently to specific poisons, which are more or less strongly marked by the symptoms of peripheral neuritis.

Professor CHARCOT said the clinical aspect of the subject mainly interested him. In lead paralysis we have wrist-drop; in alcoholic paralysis, foot-drop. In alcoholic paralysis, sensibility was affected in high degree and flying pains, not in lead paralysis. We are far from understanding the true pathology of this state, which we connect under the term peripheral neuritis. Diphtheritic paralysis, kakke, &c., are different from the other forms. In locomotor ataxy there is very often a peripheral neuritis, and it is not possible to confound this with alcoholic paralysis. There is no real difference between tabetic gait and that of alcoholic paralysis, and it is certain that what has been called peripheral tabes is alcoholic paralysis and nothing else.

Professor BROWN-SÉQUARD said that the vaso-motor nervous system has not so much power as we have for long imagined. We know now that the nervous system can influence nutrition by producing a direct chemical change. We knew gangrene was due to nervous changes, joint disease, &c., which we cannot attribute to the vaso-motor system. In an apoplectic patient we may find arteries beating with undue violence—a power of attraction; in collapse the cessation of interchange between blood and tissue, the venous blood assuming the colour of arterial. By certain substances the colour of blood may be changed in one half of the body, evidently through action of the nervous system on tissue. Inhibition can produce a cessation of activity in a vaso-motor nerve, or in a sensory or motor nerve; and outside the nervous system—e.g., a secretion—its power is much more various than we suppose. Under the term "dynamogeny" Professor Brown-Séquard has studied an increase of power by changes in the nervous system. All these things should be taken into account in studying neuritis.

Dr. GREVES (Liverpool) mentioned on behalf of Dr. Glynn two cases lately under the care of that gentleman, in both of which there was distinct evidence of neuritis, particularly affecting the cutaneous nerves of the lower extremities; and in one case there were granular kidney and cirrhosis of liver.

Dr. WHITTLE spoke of the clinical features of some traumatic cases—one in which a neuritis followed subcoracoid dislocation of the humerus. It followed the course of the musculo-spiral nerve, and produced rapid atrophy of the muscles. Another was a case of severe pain in the foot and leg, in a case of ingrowing toenail; the pain was intensified by the operation, and followed by muscular atrophy.

Dr. B. N. RAKE (Trinidad) read a paper upon the Distribution of the Leprosy Bacillus, the blood and tissues being widely examined. In no case were they found in the blood. He also described some experiments on the communicability of leprosy to animals by inoculation and feeding. The subcutaneous method was the best. The cutaneous tubercle is used, and introduced beneath the animal's skin, bacilli having been found in the tubercles employed. All the experiments yielded negative results, but differences were noticed between the results in mammals and birds, no absorption of the tubercles taking place in the latter. Dr. Rake exhibited specimens illustrating the neuritis of leprosy.

Dr. CROCKER said that Unna had observed the presence of bacilli in the cells, which had been quite disproved by Hansen, Neisner, and Toulou; but it was still an open question whether the bacilli find their way into epithelial cells. Dr. Rake's observation of paucity of bacilli in anæsthetic leprosy accords with the view of its non-contagious character. Dr. Crocker showed drawings illustrative of the anæsthetic, tubercular, and mixed form of leprosy.

Dr. CROCKER read a paper on the Anatomy of Keloid in an Early Stage. The tumour was from a man aged thirty-three, who had also multiple fibromata. The duration of the keloid did not exceed three weeks; it lay close to the site, and consisted of two unequal lobes. The tumour was surrounded by a fibrous capsule, and was divided up into lobules by bloodvessels which permeated it; the interval between the vessels being filled by a network of fibrous tissue. Laterally and below the rete the vessels were surrounded by leucocytal infiltration. The vessels became atrophied and converted into bundles of fibrous tissue. Anatomically the two kinds of keloid—true and false—are identical. The frequency of so-called "spontaneous" keloid over the sternum is attributable to liability of this region to injury. One point is the distance to which the bloodvessels are surrounded by tissue cells; thus explaining liability to recurrence, and need for wide excision.

THERAPEUTICS AND PHARMACOLOGY.

THE Address in the Section of Pharmacology and Therapeutics at the meeting of the British Medical Association at Brighton was delivered by Dr. LAUDER BRUNTON, F.R.S., who selected as his subject the "Connexion between Chemical Constitution and Physiological Action." He compared the advances which had been made in the art of treatment to the progress of civilisation as indicated by the nature of the tools or weapons employed in different ages. In the first, or Paleolithic age, man employed weapons or tools of flint, roughly chipped into shape and unpolished. In the next, or Neolithic age, the implements consisted of stone, but they were polished. The next age is characterised by the employment of bronze as a material, and the fourth and highest stage by the use of iron. In a similar manner four stages were recognisable in the development of the instruments used in the treatment of

disease. In the first stage crude drugs were employed prepared in the roughest way—such, for example, as powdered bark or metallic antimony. In the next stage these were converted into more active and manageable forms, such as extracts or solutions. In the third stage the pure active principles, separated from the crude drugs, were employed, such, for example, as morphine or quinine. In the fourth stage an attempt was made to manufacture artificially substances possessing the exact physiological action and uses required. This last stage, the iron age of pharmacology, may be said to have opened some twenty years ago, when Professor Fraser and Professor Crum-Brown of Edinburgh demonstrated the connexion between physiological action and chemical constitution, and inaugurated a new era in pharmacology. They found that by modifying the chemical constitution of strychnine they could alter its physiological action and convert it from a poison which would tetanise the spinal cord into one which would paralyse the motor nerves. At the same time that Crum-Brown and Fraser were making these experiments, Schroff in Vienna and Jolyet and Cahours in France independently arrived at somewhat similar conclusions. It would be impossible to enter fully into all the recent developments of this branch of research, but it would be of interest to review briefly what might be said to be the present position of the question. Nitrogen is a substance peculiar in this respect, that it possesses sometimes three and sometimes five "affinities," using the term in the sense in which it was employed by the scientific chemist. When combined with hydrogen in the form of ammonia or of ammoniacal salts, it affects nerve centres, motor nerves, and muscles, tending first to stimulate and then to paralyse them. But, as might be expected, the effect of the ammonia is modified by its combination with iodine, chlorine, and bromine; and it is found that while the ammonium-chloride generally attacks the spinal cord and causes irritation, ammonium-iodide paralyses the motor nerves and muscles. When nitrogen has oxygen combined with it in place of hydrogen, so as to form nitrous acid, its action is exerted more especially upon the blood and bloodvessels, so that it causes the blood to become chocolate-coloured and the bloodvessels to dilate. This power of dilating the vessels is sometimes exceedingly useful in the treatment of disease; and we are enabled to vary the action of our drugs so as to attain, to a great extent, the end desired, by our knowledge that the action depends upon the nitrous acid, and not on the substance to which the acid may be attached. Thus, where rapid dilatation is desired, nitrite of amyl is used; but where a slower and more prolonged action is desirable, nitrite of soda or nitroglycerine is employed. Carbon, again, is a substance with four affinities, while nitrogen appears sometimes to have three and sometimes five. When the nitrogen and the carbon are united in such a way that four affinities and each are connected together, leaving one free affinity belonging to penferd nitrogen, the compound is exceedingly poisonous; whereas when the free affinity belongs to the carbon and the other three affinities are joined to triad nitrogen, the compound is comparatively innocuous. This illustrates strikingly how very important the nature of the free affinity in the compound is in relation to physiological action. In the series of chemical substances to which alcohol belongs an illustration of a very striking kind is afforded. Here the carbon atoms are attached to each other by one affinity, so that each terminal atom has three affinities and the intermediate atoms two affinities unattached. All the alcohols attack the nerve centres and paralyse the brain—the spinal cord and the centres of organic life in the medulla oblongata. Primary propylalcohol, where the hydroxyl is attached to the terminal link, so to speak, appears to produce steadily increasing paralysation of the nerve centres; but secondary propylalcohol, where the hydroxyl is attached to an intermediate link, stimulates the nerve centres before it paralyses them. The whole of the carbon compounds, formed on the principle of an open chain, appear to have an action more or less like that of alcohol, though these are modified by the nature of the substances which "tip," as it were, the free affinities of the carbon links. Thus, marsh-gas, alcohol, ether, chloroform, bromoform, and iodoform, all tend to paralyse nerve centres, and to exert an anæsthetic action; but the chloral in the chloroform tends to make the substance paralyse the heart more quickly than marsh-gas, alcohol, or ether, which contain hydrogen alone or hydrogen and oxygen; and in iodoform the effect of the carbon is to a great extent swamped by the iodine. It is to Liebreich's recognition of the fact that similar carbon compounds possess a similar anæsthetic action that we owe the discovery of chloral. The knowledge of the depressing action of chlorine in such compounds upon the heart led Schmiedeberg and Cervello to search for a hypnotic substance which should not contain chlorine, with the result that paraldehyde has been added to our therapeutic *armamentarium;* and the stimulant action of ammonia led Schmiedeberg to introduce a new hypnotic, urethan, which, like chloral, will produce sleep, but, instead of weakening, will stimulate the heart, and is thus admissible in cases where chloral might be dangerous. Another good illustration is afforded by the other group of carbon compounds which is termed the aromatic series. It differs from those of the fatty groups, inasmuch as they tend to stimulate the nerve centres and produce spasms or convulsions before stimulating them. The most marked property which they possess is the power of reducing temperature, and of destroying low forms of animal life, so that they act not only as antipyretics, but as antiseptics. In the open chains of the fatty series of carbon compounds the increased number of links appears to increase the activity of the compound, and a condition which is similar in some respects is to be found in the aromatic series. For example, in phenol or carbolic acid, as it is commonly called, there is one hydroxyl terminal, just as in ordinary alcohol, the other carbon affinities being saturated with hydrogen. When these hydrogen atoms are replaced by methyl the antiseptic power of the phenol is increased, and the increase appears to be in proportion to the number of methyl groups which are introduced into the compound. In the case of antiseptics, all that is required is to ensure a thorough destruction of the microbes, which give rise to putrefaction or disease; but when we come to deal with antipyretics, we have a more complicated problem, for we wish to reduce the temperature in man or the higher animals, while, at the same time, we have to avoid producing any marked action on the nervous system in the way either of spasms or paralysis, and to avoid also depressing the circulation and causing collapse. Several bodies nearly allied to carbolic acid, and differing from it only in the fact that the benzine nucleus in them has two hydroxyl groups attached to it instead of one, as in carbolic acid, have a strong antiseptic power. These bodies are hydroquinone, resorcin, and pyrocatechin. They all have an antiseptic action, but the strength of their action is very different; resorcin being only one-third of the strength, and pyrocatechin only one-fourth of that of hydroquinone. This difference in strength shows here, also, how important the position of the hydroxyl groups is; because in pyrocatechin they are close together, in hydroquinone they are as far apart as they can be, and in resorcin they keep an intermediate position. These bodies with their simple structure appear to be too well adapted to attack all parts of the animal organisation, and they are apt to affect the nervous system and circulation. In order to avoid these disadvantages, various attempts have been made to obtain bodies of a similar but more complicated structure, which should have a more specialised action, and would lower the temperature and leave the nervous system and circulation unaffected. These attempts have been more or less successful, and we owe to them the introduction of three new remedies—kairin, thallin, and antipyrin. The former two, after a brief period of trial, have been found more or less unsatisfactory, but the latter is perhaps, upon the whole, the best antipyretic that we possess, reducing the temperature, and, at the same time, having few disadvantages. Salicylate of soda is nearly allied in chemical constitution to resorcin, and as a general antipyretic it is almost equal to antipyrin, and superior to it in cases of rheumatic fever. It is possible that we may still obtain antipyretics more powerful than any we yet possess, and specially adapted to the febrile conditions arising from different causes, for these antipyretics do not appear to be equally successful in different kinds of fever. Antipyrin is best in hectic fever, salicylate of soda in rheumatic fever, but an antipyretic which will be thoroughly satisfactory in typhoid fever is still a desideratum. Antipyrin is generally free from any disagreeable action, but this is not always the case, for it sometimes produces collapse. This shows that in the action of all drugs there are two factors to be considered: the drug itself and the body into which it is introduced. The failure of our drugs to produce the effects we desire is one of the most trying occurrences in medical practice. Thus, in fever we some-

times find that drugs will not reduce the pulse as they do in non-febrile conditions, and digitalis in pneumonia sometimes appears to have lost its sedative action on the heart altogether. This failure of digitalis to slow the pulse in febrile conditions is due to paralysis of the regulating nerves of the heart, the part affected by the heat being that connected with the medulla. It was found that the muscle of a frog poisoned by barium could be restored to its normal condition by a high temperature, and also by the application of salts of potassium. If the body of an animal be saturated with potassium, it is rendered proof against the poisonous action of barium. Dr. Cash, following up this line of research, has recently demonstrated that an animal inoculated with the powerful antiseptic, corrosive sublimate, is capable of resisting the power of anthrax. These experiments derive additional interest from the fact that Pasteur is now inclined to think that his process of inoculation, which has produced such wonderful results in hydrophobia, is effected by means of an agent which is in reality a chemical substance, and not a microbe. The lecturer concluded with these words:—"When we look back for twenty years and see how far pharmacology has advanced since Crum-Brown and Fraser's experiments directed it into a new path, we may hope that twenty years more may not only have greatly added to our stock of new remedies, but will have enabled us so to ascertain the condition of our patients that we may ensure the action we desire either by the proper modification of a single remedy, by the proper admixture of remedies, or by proper changes in food or surroundings of each patient; that we shall not have to feel, as we painfully do at the present, that our patients often die for lack of knowledge, not on our part, but on that of our art. Nothing is more painful to a medical man than having to answer in the negative to an agonised appeal 'Oh, doctor, can you do nothing?' of those who see passing away those who are dearer to them than their own life. It is because we know the value of human life and the extent of human suffering, because we are called upon to prolong the lives of those not only their friends but their country and the world at large can ill spare, and to relieve pain sometimes amounting to extreme torture in the sufferers themselves, and felt hardly less keenly by their friends, that we consider it is not only permissible, but it is our imperative duty, to gain the knowledge we require to attain our object, even though we sacrifice the lives of animals, and inflict upon them small pain, never wantonly, never carelessly, and almost always slight in comparison with that we often see our patients feel. Moreover, the lower animals suffer from disease as well as men, and we may hope that the advance of pharmacology will give us the means of relieving pain and prolonging life in them as well as in man."

At the conclusion of Dr. Lauder Brunton's address, Professor LIEBREICH of Berlin read a paper on "Lanoline, a new Fatty Substance; its Physical Properties and Therapeutical Uses." After referring to the enormous progress which had been made in the study of pharmacology and therapeutics during the last few years, he pointed out that the importance of local treatment in many diseases had received little attention. Ordinary inunctions were of comparatively little value, but lanoline differed from common fat in that it contained cholesterine and not glycerine, and consequently assimilated more closely to the natural composition of the body. It was a very stable chemical compound, and was not decomposed by boiling with alkaline solutions. It was extracted from the fat contained in wool, and in a crude and imperfect form had long been employed in veterinary practice under the name of "wool oil." It absorbed water very readily, and could be rubbed into the skin without difficulty. It was very valuable indeed as an adjuvant in massage, and had this great advantage, that there was no necessity for washing the skin afterwards as when fatty substances were used. It was useful in all forms of skin diseases, whether local or constitutional. The great difficulty was to get it pure; chemists often supplied the wrong article or inferior kinds which gave rise to much irritation. He had frequently seen this, and in one case which had come under his notice in consultation a crop of acne spots had resulted from the use of an adulterated form. The pure lanoline had great powers of penetration, and might be used as a vehicle for the introduction of mercury and other drugs into the system. The great point to remember was that it was a neutral body freely miscible with water. Professor Liebreich concluded his paper, which was listened to with marked attention, by demonstrating the points of difference between good and bad lanoline.

Dr. JOHN V. SHOEMAKER (Philadelphia) said that his attention had been first directed to the subject in 1879, and had occupied him considerably since then. He had referred to it in the paper which he read before the British Medical Association at its meeting in Belfast in 1884. He had no doubt that animal fats were the best adapted for deep penetration. Lanoline was mild and soothing in action, and was reliable in a great number of obstinate skin diseases. He had used it personally with great success in alopecia, chronic eczema, boils, and carbuncles.

Dr. MACKEY (Brighton) said that lanoline in his hands had given the most marvellous results in the treatment of chronic joint affections, especially those of rheumatic origin. An ointment of iodide of potassium made with lanoline reduced swelling of the joints and gave prompt relief to pain. In psoriasis it was well-nigh a specific, whilst in chronic enlargement of the glands of the neck nothing could be better.

Dr. JOHN V. SHOEMAKER (Philadelphia) contributed an able paper on the Witch Hazel (*Hamamelis Virginica*) and its therapeutic uses. It had long been used, he said, as a domestic remedy, but was in reality a powerful therapeutic agent worthy of the attention both of physicians and surgeons. It was not only anodyne, but hæmostatic. It was employed in America in many forms—not only in the forms which were officinal, such as the liquid extract, but also as hazeline, which was an aqueous distillate. If it failed it was from being used in inappropriate cases. It was said by some that the good effects were due to the spirit contained in the preparations, but such was not the case, for he had tried weak alcoholic solutions against the hamamelis, and had no hesitation in saying that the latter was incomparably superior. The solutions of hamamelis contained a volatile oil, on the presence of which much of the activity depended. Perhaps some of the failures were attributable to the fact that insufficient quantities were given. It was not only an astringent, but an astringent tonic. It was not generally known that it was a cardiac sedative. He had found it act like magic in hæmorrhage after the failure of quinine, ergot, and a number of other drugs. It would check bleeding after parturition, especially when it assumed a chronic form. In chronic epistaxis it would often save life when other remedies were hopeless. He had used it in two cases of hæmophilia with absolute success. In hæmorrhage from the bowels, purpura, and many similar conditions it might be relied on absolutely. He had seen good results from its use in varicose veins, and had cured eleven out of seventeen cases of varicose ulcer by it alone. It was useful in chronic diarrhœa, leucorrhœa, and gonorrhœa; nothing was better in some forms of acne. In America it was largely used in the treatment of chronic naso-pharyngeal catarrh, and also as a mouth-wash.

Dr. POLLOK (Glasgow) fully corroborated Dr. Shoemaker's statements, and said that he had found hazeline useful in a great number of cases. Its good effects might to some extent be due to the terebene it contained.

OPHTHALMOLOGY.

Mr. CHARLES OLDHAM, President, after welcoming the Association to Brighton, and briefly reviewing the ophthalmological work of the past year, spoke as follows:—"The last time the Association met in Brighton was in the year 1851. There was then no Ophthalmic Section. Nearly thirty years were to elapse before the Association, which at that date numbered only about 1700 or 1800 members in all, could boast of a body of its associates who devoted their time and abilities to the sole study and practice of the surgery of the eye. But that year was destined to be a memorable one in ophthalmic annals; for it was in 1851 that the great Helmholtz brought out the instrument of which it may be said (and it is an excellent illustration of Schopenhauer's just remark, that all great thinkings are apparently obvious in proportion to their greatness) that its principle was apparently so obvious that we marvel it had never been thought of before. I need not point out to you the entire change that has been wrought in our art by this discovery. It will suffice to say that diseases which, before its advent, were so many additions to nomenclature, and to nomenclature only, have now become objective entities to the surgeon as well as to the patient.

It is as alien to what I conceive to be my province to make you any learned address on the more recondite and controversial points of our art—for we have before us for our consideration a series of papers and discussions which promise much in that direction—as to anticipate in any way the matter contained in these contributions. We shall undoubtedly listen to them with great interest, as they will give us the experience of others on questions which each one of us has frequently attempted to solve, and has also lamentably failed more than once at least in the enterprise. I note with some regret the absence in our list of any paper on the best mode of treatment of simple chronic glaucoma. Now that we have been enlightened by the labours of Priestly-Smith, Brailey, Landolt, and others, as to the etiology of this formidable affection, the advancement of our knowledge should bear fruit in the direction of some mode of dealing with the problem set before us, other than by iridectomy pure and simple, the results of which are very far indeed from satisfactory. Is there any hope that some other method of counterbalancing drainage, at once unirritating and effective, may be devised? At present, eyes so affected would seem to be best left alone. Have we learnt anything in the past year with regard to suppuration after operation? Would he not render a great service to mankind who should give us, by some process of generalisation, amongst other precepts, rules for the kind of incision to be made in various operations, but principally, of course, in that for cataract in different individuals—whether such incisions should be severely corneal, or in the sclero-corneal junction,—to give us, in short, some indications which should guide us as to the likelihood of consequent suppuration? It is certainly given to individuals, now and again, to possess what, for want of a better name, may be called an instinct in such matters. As a pointed example of this power of selection by instinct, I may cite the case of Antonius Stradivarius of Cremona. This great master, by the sense of touch alone, was able to divine the relative acoustic merits of the wood from which he made his hitherto unrivalled violins. The late Mr. Critchett possessed a rare instinct for the selection, not only of cases which were suitable for operation, but also of the particular mode of operating which should best favour success; but, like Antonius Stradivarius, he was apparently unable to convey the method of his secret to others. I cannot but think that this selective instinct, which has been given to few, may in course of time be formulated for general use. In this connexion it is pertinent to ask how far we are agreed upon the value of antiseptic measures in operations on the eye; and whether, conceding the value of these measures, out of many agents we possess for the purpose, there are any solutions of greater antiseptic virtues, and with fewer drawbacks, than those of the perchloride of mercury and boracic acid? One of the main objects of every Society of Oculists is the propagation of such knowledge of ophthalmic surgery, amongst those who do not enjoy their special advantages as will enable them to avoid being pointed at as the authors of cases of preventable blindness; and also by a routine acquaintance with the ophthalmoscope, to add a factor, or factors, to the items of evidence which they already possess towards forming a just estimate of many cases which must necessarily pass through their hands in the course of the working year. I venture to think that this has lately been, and is now being, very effectually done. Such cases as those I have referred to are becoming rarer every day, and I am frequently surprised at the amount and accuracy of ophthalmological knowledge to be met with at the present time amongst those who are not specialists, as compared with the acquirements in this direction of a very few years back. Ours is, indeed, one of the noblest of sciences. The blind have ever been considered amongst all nations and in all ages to be the class that most appeals to the commiseration and sympathy of mankind. It is, with us, not only a plain-sailing duty in the legitimate exercise of our profession, but also a pleasure of the acutest kind to relieve the necessities of those who call upon us in this respect for aid. The trustful confidence with which blind humanity invariably relies upon the everyday assistance of its brother man, even in the guise of a stranger, is a very marked feature of this particular affliction.

IT was resolved at a special meeting of subscribers, held on the 6th inst., to enlarge the premises at present occupied by the Bristol Eye Hospital.

Pharmacology and Therapeutics.

ANHYDROUS HYDROCHLORATE OF COCAINE.

WE have examined and used the sample of anhydrous crystals of hydrochlorate of cocaine which Messrs. M'Kesson and Robins, of 38, Mark-lane, have forwarded to us. The crystals were well formed, dissolved readily in distilled water, and proved to be free from impurity. The 20 per cent. solution which we prepared from it answered its purposes admirably. The crystals are sold in small phials containing one gramme each, and the cost of twelve grammes is one guinea.

COCAINE PELLETS.

Mr. W. E. Sacker, of Fenchurch-street, E.C., calls our attention to his compressed cocaine pellets for the treatment of bronchitis and laryngeal complaints. They contain in each four grains of chlorate of potassium, one grain of extract of liquorice, and one-sixtieth of a grain of cocaine. The compound cocaine pellets contain borax, chloride of ammonium, bicarbonate of sodium, and one-twentieth of a grain of cocaine. They are both somewhat roughly made, but the formulæ are good, and would undoubtedly prove applicable to many cases.

PURE TEREBENE.

We have received from Messrs. C. J. Hewlett and Son a specimen of their pure terebene. On examination it is found to be colourless, to have an agreeable odour, pleasant taste, and to be entirely volatile. It is well adapted for internal administration, and is an improvement on most of the so-called terebenes which were at first manufactured.

BUSH AND CO.'S SANDAL-WOOD OIL.

We have received from Messrs. W. J. Bush and Co. a sample of their pure drawn English oil of sandal-wood. It is undoubtedly a very pure specimen, and is admirably adapted for use as a medicinal agent.

ANTIPYRINE IN PEDIATRICS.

In the policlinique of Rio Janeiro, Professor Moncorvo has tested the value of antipyrine in infantile therapeutics by administering it to more than one hundred children of various ages, the youngest being only thirteen days old. The principal diseases treated were bronchitis, bronchopneumonia, tuberculosis, acute rheumatism, and some surgical affections associated with suppurative fever. As much as from two to three grammes of the agent were given every hour or two, and repetition regulated by half-hour thermometric observation. No toxic effect was observed, and defervescence was rapid and regular. Antipyrine may be employed hypodermically, and when administered by the mouth may be combined with quinine, the absorption of which it appears to facilitate.

BROMINE IN DIPHTHERIA.

Señor Lovat A. Mulcachy of Buenos Ayres finds great advantage in cases of diphtheria in giving a solution of bromine. The bromine is simply dissolved in water in the proportion of 1 to 2500. A teaspoonful of this is given every ten minutes. He says that children will swallow it automatically even when asleep. For infants under three years of age the strength may be diminished to half that mentioned above. He cites several cases showing the successful results obtained by this method, but he points out the importance of the administration being continued for some days, and of the medicine being given exactly every ten minutes. As to local caustic applications, he considers that they serve no purpose whatever, but only irritate and distress the patient.

TAR BANDAGES.

Dr. Prokhoroff, writing in the *Vrach*, speaks very highly of the advantages of tar bandages in compound fractures and suppurating wounds. The material used for the bandage is gauze, and, after this has been applied, it is well smeared over with the tar brush. The dressing is not changed but fresh tar is applied daily. The cases in which this method

has been employed are not as yet very numerous, but Dr. Prokhoroff hopes that other surgeons will give the plan a trial.

ACTIVE PRINCIPLE OF BONDUC SEEDS.

A bitter principle has been extracted from the bonduc seeds of the Indian Pharmacopœia in the form of a white bitter powder, soluble in alcohol and chloroform, and nearly soluble in water. It dissolves in fixed and volatile oils. In doses of from ten to twenty centigrammes it has proved of value equal to quinine in the treatment of intermittent fever.

CAMPHOR, CHLORAL, AND COCAINE IN TOOTHACHE.

Dr. K. Gsellfels recommends in toothache with hollow teeth a plug of cotton-wool saturated with a mixture made by heating five parts of camphor, five parts of chloral hydrate, and one part of hydrochlorate of cocaine to boiling for some minutes. An oily liquid is obtained.

REPORT
OF
The Lancet Sanitary Commission
ON
SMALL-POX AT WINDSOR.

THE Special Commission Report on the Housing of the Windsor Poor which we published on Aug. 15th, 1885, has, within less than a year, received disastrous confirmation. Some slight improvements have taken place in the interval. Prospect-place is condemned, a few new closets have been built, and there is a little more activity in respect to cleaning and whitewashing. Nevertheless the scandal of the exposure has not done much good. In the main, matters remain in the same state as at the time when we first described and denounced the insanitary condition of various slums, but especially South-place and its surroundings. Here, and in Bier-lane, small-pox and cholera had each in its turn wrought havoc; but it was stated, in reply, that during the last five years there had been no death from zymotic disease in the incriminated districts. These statistics related, however, to an average population of only 170 persons, and did not therefore include all the districts we condemned. Nevertheless, and whatever may have been the value of such an argument, it is now no longer available. During the last two or three months small-pox has prevailed in the very parts of Windsor to which we pointed as constituting a permanent public danger. At 4, Charles-place, which is but the continuation of South-place, described in our special report, a man died of small-pox during the hot weather of last July. The clergyman who visited this unfortunate man informed us that he found him lying on some wood shavings in a back room, where no ventilation existed. Instead of an immediate burial and a plentiful supply of disinfectants, the body was allowed to remain for some days in this awful rookery, so that the surrounding atmosphere was still further poisoned. When, at last, the body, without disinfectants, was brought for burial, even the undertaker refused to put a pall over so foul a coffin. Without this last sign of respect the poor man was buried, and the clergyman who performed the ceremony has suffered from sore-throat since. Charles-place consists of five houses, facing Charles-street. There is a small yard behind and three more houses. These eight houses have for the use of their occupants but three closets and no dustbin. The dust and refuse are thrown recklessly about. A mound, apparently of refuse well-trodden down, rises above the level of a little hutch used as a barber's shop. The rain must drain from this mound of dirt into the basement of the hairdresser's establishment. The barber pays £16 a year for this miserable shanty, and a so-called four-roomed house. But the ceilings of the rooms are so low that a tall man cannot stand up in them, and two of the four rooms measure about 9 ft. by 7 ft. Here people came to be shaved during the dog days, and enjoyed the refreshing operation within a few yards of the decaying corpse of a small-pox patient.

On visiting this mournful locality last week, we found that the house No. 4, Charles-place, was undergoing the process of fumigation. No. 17, Charles-street, almost opposite, was also abandoned, the people who had suffered from small-pox having left. No. 28, where there had been cases of small-pox, was also evacuated; but altogether, in this small clump of houses and within a radius of fifty yards, we found the record of eleven cases of small-pox. A few steps further, in Oxford-road on one side and in South-place on the other side, there were also cases, and we noted that a small shop in Oxford-road was shut up in consequence. We were further informed that there had been cases of small-pox in Victoria Cottages, in Bridgewater-terrace, in Arthur-road, in Church-street (close under the Castle walls), and in Love-lane (close to the barracks), but the Windsor authorities have, however, taken extraordinary measures to stamp the disease out, and it was resolved to isolate the cases in spite of all obstacles. Orders were given that not only should the sick remain in their miserable hovels, but that all the other tenants should be kept there close to the source of infection. Watchmen were posted outside the houses, and the inhabitants made prisoners, so that they should not carry the disease elsewhere, though such a measure rendered it likely that they would themselves contract the disorder. The value of this precaution, from a sanitary point of view, we do not at present propose to discuss. At No. 31, South-place, where seven persons lived in a very small house, we were informed that all the inmates, with the exception of a man who worked in the open fields, were confined on the premises. This caused a youth who had been employed as an errand boy in a shop for four years and a half to lose his place, and a young woman who had just secured an engagement as domestic servant had to give up her situation. We maintain that all those who have suffered through the epidemic, who have been confined to their houses so that the disease should not spread, have a right to compensation. But for the long delay in compelling the owners of property to do their duty towards their tenants, this epidemic would probably not have gained ground. It is stated that the first cases were imported by tramps; doubtless. We are not aware that small-pox is of spontaneous growth. But why was there no means of isolating these tramps—no fever hospital; and why are rookeries so long allowed to exist where zymotic germs find a fertile soil for their development?

In the month of March last a grand meeting was held. It was announced that a company would be formed under Royal patronage, and that the Bier-lane district would be pulled down and rebuilt. In a month's time another meeting would be convened and progress reported. Four months have now elapsed; there has been no other meeting, and no progress whatsoever is reported. We protest against this Bier-lane scheme as utterly inadequate to meet the exigencies of the situation. Bier-lane is certainly not the worst part of Windsor, and South-place should be first attacked. It is said that land owners and house owners claim too heavy compensation. Let the Sanitary Act be applied with the utmost and with constant rigour, the owners of this foul property will then be glad enough to get rid of it at any price. In one way or the other these Royal rookeries must be done away with, both those that are within fifty yards and those that are within five hundred yards of the castle. The danger of infection is almost equal in either case. During the last few weeks the small-pox has travelled from these slums to within a few yards of the castle walls, and close to the barrack gates. We have to consider the health not only of the Royal family, but of the *élite* of our troops quartered all the year round at Windsor. Reform in Bier-lane will not suffice to remove the dangers with which they and the ordinary inhabitants of the town, the innumerable visitors and tourists, are menaced; and, as the authorities at Windsor are so slow to move, we trust pressure, official pressure, will be brought to bear from without.

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.—The fifty-sixth annual meeting of the members of this Association is to be held at Birmingham, from the 1st to the 8th prox. On the 2nd and 3rd ult., the Ingleby Lectures on "Recent Advances in Abdominal Surgery" will be delivered by Mr. Lawson Tait, admission to which may be obtained by medical members and associates of the Association. A lecture by Professor W. Rutherford, M.D., on "The Sense of Hearing" is also announced for the 3rd prox.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns 5397 births and 3472 deaths were registered during the week ending August 7th. The annual death-rate in these towns, which had slowly increased in the preceding seven weeks from 16·8 to 20·6, declined again last week to 19·9. During the first five weeks of the current quarter the death-rate in these towns averaged 19·8 per 1000, and was 1·7 below the mean rate in the corresponding periods of the ten years 1876-85. The lowest rates in these towns last week were 10·0 in Halifax, 10·4 in Hull, 10·8 in Derby, and 15·0 in Plymouth. The rates in the other towns ranged upwards to 24·1 in Blackburn, 24·4 in Manchester, 28·9 in Norwich, and 31·4 in Leicester. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had steadily increased in the preceding eight weeks (owing to the rising mortality from infantile summer diarrhœa) from 263 to 872, was last week 869; they included 657 from diarrhœa, 62 from measles, 55 from whooping-cough, 48 from scarlet fever, 38 from "fever" (principally enteric), 13 from diphtheria, and one from small-pox. The lowest death-rates from these zymotic diseases were recorded last week in Hull and Derby, and the highest in Leeds, Norwich, and Leicester. The mortality from diarrhœa in the aggregate of the twenty-eight towns differed but slightly from that recorded in the previous week; the largest excess occurred in Birkenhead, Leeds, Norwich, and Leicester. Measles caused the highest death-rates in Preston, scarlet fever in Salford, whooping-cough in Manchester and Norwich, and "fever" in Cardiff and Portsmouth. Small-pox caused one death in Liverpool, but none in London and its outer ring or in any of the twenty-six other large provincial towns. The number of small-pox patients in the metropolitan hospitals situated in and around London, which had been 13, 11, and 10 on the preceding three Saturdays, had further declined to 8 at the end of last week; 2 cases were admitted to these hospitals during the week, against 2 and 1 in the previous two weeks. The deaths referred to diseases of the respiratory organs in London, which had been 163 and 172 in the preceding two weeks, declined last week to 148, and were 44 below the corrected average; this was a lower number of deaths from these diseases than have been returned in any week since the beginning of this year. The causes of 73, or 2·2 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Birmingham, Newcastle-on-Tyne, Sunderland, and in five other smaller towns. The largest proportions of uncertified deaths were registered in Halifax, Oldham, Salford, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 19·8 and 19·5 per 1000 in the preceding two weeks, declined to 18·8 in the week ending August 7th; this rate was 1·1 below the mean rate during the same week in the twenty-eight English towns. The rates in the Scotch towns last week ranged from 11·5 in Perth and 14·4 in Dundee, to 20·5 in Glasgow and 25·2 in Paisley. The 464 deaths in the eight towns showed a decline of 17 from the number in the previous week, and included 28 which were referred to diarrhœa, 23 to whooping-cough, 15 to scarlet fever, 8 to "fever" (typhus, enteric, or simple), 2 to diphtheria, 1 to measles, and not one to small-pox; in all, 77 deaths resulted from these principal zymotic diseases, against 65 and 67 in the preceding two weeks. These 77 deaths were equal to an annual rate of 3·1 per 1000, which was 1·9 below the mean rate from the same diseases in the twenty-eight English towns. The deaths attributed to diarrhœa, which had increased in the preceding seven weeks from 8 to 34, declined again last week to 28, of which 10 occurred in Glasgow, 7 in Edinburgh, 5 in Dundee, and 3 in Paisley. The annual death-rate from diarrhœa in these eight Scotch towns last week did not average more than 1·1 per 1000, whereas the mean rate from the same cause in the twenty-eight English towns was 3·7. The 23 fatal cases of whooping-cough showed an increase of 5 upon the number returned in each of the three preceding weeks, and included 18 in Glasgow and 2 in Aberdeen. The 15 deaths from scarlet fever showed a considerable increase upon the recent weekly numbers; 13 were returned in Glasgow, against but 5 and 3 in the previous two weeks. The deaths referred to "fever," which had been 4 and 1 in the previous two weeks also rose last week to 8, of which 4 occurred in Glasgow. The fatal cases of measles and diphtheria were below the average. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had declined in the preceding seven weeks from 93 to 63, further fell last week to 58, and were 4 below the number returned in the corresponding week of last year. The causes of 58, or nearly 13 per cent., of the deaths in the eight towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 21·0 and 17·3 per 1000 in the preceding two weeks, was 17·6 in the week ending Aug. 7th. During the first five weeks of the current quarter the death-rate in the city averaged 19·7; the mean rate during the same period was 20·9 in London and 19·2 in Edinburgh. The 119 deaths in Dublin last week showed an increase of but 2 upon the low number in the previous week, and included 7 which were referred to scarlet fever, 3 to diphtheria, 2 to "fever," 2 to diarrhœa, 1 to whooping-cough, and not one either to small-pox or measles. Thus, the deaths from these principal zymotic diseases, which had been 12 and 5 in the preceding two weeks, rose last week to 15, and were equal to an annual rate of 2·2 per 1000, the rates from the same diseases being 5·9 in London and 2·0 in Edinburgh. The 7 deaths from scarlet fever showed a considerable increase upon recent weekly numbers, and exceeded the number in any previous week of this year. The fatal cases of diphtheria also showed an increase. The deaths attributed to diarrhœa were considerably below the average for the season. Two inquest cases and 2 deaths from violence were registered; and 41, or more than a third of the deaths, were recorded in public institutions. The deaths of infants and of elderly persons showed a considerable decline from recent weekly numbers. The causes of 10, or more than 8 per cent., of the deaths registered during the week were not certified.

Correspondence.

"Audi alteram partem."

NERVE-STRETCHING FOR LEPROSY.

To the Editor of THE LANCET.

SIR,—In your issue of June 5th is a brief report of a paper read before the Harveian Society by Dr. Downes. The question was asked how long the improvement continued after nerve-stretching. I still occasionally meet with cases operated on by Dr. Downes six or seven years ago. Many of these continue to have good sensation, others of them return for the purpose of having the operation repeated. Certainly in a large proportion of cases the benefit is permanent, and in very few indeed is the recurrence rapid or complete. In the *Edinburgh Medical Journal*, two years ago, I published an account of 170 nerve-stretchings which included Dr. Downes' cases. Any who are interested in the practice can refer to that paper; the theory has yet to be elucidated. I am, Sir, yours truly,

Kashmir Mission Hospital. A. NEVE, F.R.C.S. Ed., &c.

THE BEAUFORT LEG.

To the Editor of THE LANCET.

SIR,—Your issue of the 17th ult. contains a paragraph headed "A Modified Beaufort Leg," which ends by stating that Mr. Schramm sells the modified limbs at considerably less price than the original. Now, as one who has had above six years and a half practical and intimate experience of the "original" Beaufort leg, having ordered and paid for upwards of eighty specimens, perhaps you will do me the favour to allow me an equally prominent position with the original statement in your journal to deny the assertion so confidently made. The original leg, which has stood the test of some twenty years' experience, costs, when made by

Mr. E. Werber of Paris, the sole French manufacturer, from 32*s.* to 36*s.* Mr. Schramm's charges are 70*s.* to 90*s.*! One of the great merits of the Beaufort leg, indeed, *the* object of the invention, was cheapness, so that it might be given by the charitable to poor cripples. The modification of the Beaufort leg, however advantageous in use, is certainly not so in cheapness.—Yours faithfully,

HENRY H. MAXWELL,
London, Aug. 5th, 1886. General, Royal Artillery.

THE MEDICAL ACT OF 1886.

To the Editor of THE LANCET.

SIR,—Since a copy of this Act appeared in your issue of 3rd July I have anxiously looked for an expression of opinion from some member of the profession, but so far as I am aware *no one has as yet written either favourably or otherwise of this piece of legislation.* If I interpret the Act correctly, it signifies that we may at any time expect men who possess an M.D. from some *American degree-granting University* to settle in our midst. As these *gentlemen* have neither expended the time nor money necessary to acquire any medical qualification obtainable in Britain, they will be able and willing to give their services at a low rate; they will, moreover, have the advantage of being thought by people generally to be better qualified to treat sickness than, for example, an M.B. or an M.R.C.S., owing to their being "Doctors of Medicine." It surely cannot be too late to prevent such an injustice being thrust upon us. If some eminent member of the profession will raise his voice against this iniquitous Act, he will, I feel certain, be supported by every legally-qualified practitioner in Britain, and will, moreover, earn our lasting gratitude and, I hope, something more substantial.

I am, Sir, yours faithfully,
Aug. 4, 1886. NEMO.

*** The recognition of foreign degrees will be one of the most serious duties of the Council under the new Act.—ED. L.

NORTHERN COUNTIES NOTES.

(*From our own Correspondent.*)

NOTIFICATION OF INFECTIOUS DISEASES.

MR. A. E. HARRIS, the medical officer of health for Sunderland, said in a paper read last week at Gilsland that "he considered it strange the people of this country had not yet generally adopted laws for their protection from diseases which were spread by infection. He knew well that Parliament was very jealous of enacting laws which interfered in any way with the liberty of the subject; but he was also aware that when persons suffering from infectious diseases unnecessarily exposed themselves, they were degenerating their liberty into licence, and he thought it strange that while a paternal Government insisted that if an unfortunate pig should unhappily contract swine fever the animal was fenced round with all kinds of restrictions to prevent the disease spreading to any of its kind, yet that it did nothing, and had done nothing, to insist on the greatest care being taken that infectious diseases should be carefully separated from the public." Mr. Harris, in the course of his paper, went on to show that the Medical Department of the Local Government Board was entirely in favour of the principle of notification. He stated that the compulsory notification took effect on the 1st of September last, and mentioned sixty-two cases which had come under his notice where disease occurred in places of business at Sunderland, which might very easily consequently have become centres for the spread of disease. Mr. Harris further said that since the notification of infectious diseases had been introduced in Sunderland infectious diseases had been less than at any period during the last twenty years.

MEASLES AND GOSSIPING.

At the late meeting of the Hebburn Local Board the subject of the present epidemic of measles came under consideration. The medical officer stated that the outbreak of measles at the Hebburn Colliery was very serious. Nine deaths had taken place, but the disease gave signs of abatement. At the same time, it was very difficult to prevent the spread of the disease, owing to the gossiping nature of the inhabitants. The houses were invariably to be found with open doors, and the neighbours entered the first one they came to, and sat down.

THE FLEMING MEMORIAL HOSPITAL.

A further step in progress has been made towards the erection of the hospital proposed to be built in Newcastle by Mr. Fleming, a munificent citizen, for sick children. Mr. Currey, architect of St. Thomas's Hospital, London, having been appointed to advise Mr. Fleming in the matter of the competition of designs for the hospital, the former gentleman has given the first place to the design of Messrs. Quilter and Wheelhouse of London, so that we hope very soon to see the foundation-stone laid.

At a meeting of the Jarrow Town Council last week it was finally decided to accept tenders for the erection of a hospital for infectious diseases in the borough. The question, it was stated, had been under discussion for nearly twenty years.

Newcastle-on-Tyne, Aug. 2nd.

EDINBURGH.

(*From our own Correspondent.*)

POST-GRADUATE COURSE IN EDINBURGH.

THE programme for this course of Clinical Instruction, which is arranged to extend from September 27th to October 16th, is now completed. Thirteen separate subjects are to be taken up and illustrated clinically or experimentally; in some of them there will be the option of attending one or other of a series of cliniques in different departments—this, however, only where the amount of material at command is so great that subdivision of labour will be advantageous, as in general medical and surgical diseases; in other subjects, where this is not the case, arrangements for amalgamation and concentration of material have been made. Special courses will be given on dental diseases, the diseases of children, gynæcology, diseases of the ear and throat, of the eye, and of the skin, syphilis, mental diseases, general medical and surgical diseases, and upon pathology. Six demonstrations on the regional anatomy of the viscera and organs are also arranged for. The hours for the various demonstrations have been arranged, so far as may be so as not to clash with one another; and a chart has been prepared giving ready information as to the time, day, and place of meeting of each of the classes in the course. The charts and further particulars are obtainable upon application to either of the secretaries, Prof. Chiene and Dr. Claud Muirhead, of Charlotte-square, Edinburgh. A large number of old Edinburgh students have already announced their intention of attending the course, and there is every prospect of its being in all respects a great success.

GRADUATION THESES.

At the annual Graduation in Medicine which took place last week, forty-nine Bachelors of Medicine of the University of Edinburgh were promoted to the degree of M.D., upon their presentation of theses dealing with medical or scientific subjects. Five of these dissertations were of such merit as to earn for their authors University Gold Medals, the highest distinction in medicine conferred by the University upon its alumni. Two of these theses, those of Dr. William Hunter and Dr. Edward Carmichael, were upon the subject of the transfusion of blood, both containing original and valuable results derived from experimental research. Dr. MacFadyean presented a thesis upon the behaviour of bacteria in the digestive tract, the outcome of investigations carried on in the laboratory of Professor Fluegge, and of special interest at present from the relation it bears to the discussions which are now taking place upon the etiology of cholera. Dr. A. M. Paterson's thesis is upon the spinal nervous system of the mammalia, and is a contribution to anatomical science from the Manchester Medical School, in which he is senior demonstrator of anatomy. Dr. Stockman in his thesis considers the action and therapeutic value of vegetable astringents, giving the results of investigations carried on in the Materia Medical laboratories in the University of

Edinburgh. In addition to these five thesis, which were deemed worthy of gold medals, were a number specially commended for the excellence of the work contained in them, amongst which are Dr. Lang's upon the knee-joint, and Dr. Clemow's upon the infective granulomata. The whole of these theses find their way into the University archives, where in general they pass through an undisturbed existence, for as theses they are never published. Fortunately, however, they are not altogether committed to oblivion, for in the form of summaries, extracts, or at times in lengthy papers, the pith of their contents finds its way into current numbers of one or other, occasionally even several, of the leading medical journals, and data often of considerable importance are thus added to various branches of medical science.

Edinburgh, August 10th.

IRELAND.

(From our own Correspondent.)

VICERREGAL APPOINTMENTS.

THE following appointments have been made by his Excellency the Marquis of Londonderry:—Physician in Ordinary: Dr. Hatchell. Surgeons in Ordinary: Philip Crampton Smyly and Edward Hamilton. Surgeon to the Household: Thomas Nedley. Surgeon Dentist in Ordinary: Robert H. Moore. Surgeon Dentist: A. H. Jacob.

ROYAL UNIVERSITY OF IRELAND.

At a meeting of the Senate last week the death of Dr. Curtis, who had been re-elected as senator as late as July 27th, having been reported, a resolution was unanimously adopted, expressing the regret of the Senate for the loss of so valuable a member, and their sympathy with his family in their bereavement. The Senate have appointed October 27th next for the annual meeting of Convocation, when the vacancy in the Senate will be filled up. Dr. William Thomson has been elected a member of the Standing Committee.

SOUTH DUBLIN UNION.

At a meeting of the guardians last week a communication was received from Dr. H. Stevens, Inspector to the Local Government Board, England, to the effect that he had been instructed to visit Dublin, in order to inquire into the arrangements for public vaccination, and to report to his board with the view to the recognition by the board of the certificates of proficiency in vaccination that may be given by a public vaccinator to be selected by the board. Dr. Stevens will be in Dublin on an early day, and the clerk of the union has, at his request, furnished him with particulars of the vaccination arrangements in the union.

THE BELFAST RIOTS.

There were, on Monday last, thirty-seven persons injured by gunshot wounds remaining under treatment in the Belfast Royal Hospital. About twenty-seven of these cases were admitted on Saturday, and ten on Sunday. In addition, fifty persons were treated for gunshot wounds in the extern department of the hospital.

SEVERE BULLET WOUND; RECOVERY.

The case of Head Constable M'Coldrick, of Dundrum, county Tipperary, is worth noting. On July 12th the constable shot himself with a revolver; the bullet entering half an inch under the heart, passed entirely through the body, and emerged at the back, close to the spinal column, being found immediately after the occurrence in the man's clothes. The patient has now quite recovered, and has resumed duty.

RATHDOWN UNION.

Mr. Robinson, Local Government Board Inspector, in his recent report on the condition of this workhouse, states that with regard to the lunatics located in the institution he has carefully considered the recommendations of the committee of the guardians dealing with this matter. He is convinced that unless a paid attendant is appointed and placed in charge of this department, there is no security that the directions of the committee will be properly and stringently carried out. Our readers will bear in mind the recent case of manslaughter by a lunatic inmate of the workhouse, which in the opinion of the coroner's jury was attributable to the want of efficient supervision in this department. The Local Government Board have written to the guardians suggesting that the recommendation of their inspector should be carried out, but the guardians appear to consider that their present arrangements are ample to meet all necessary requirements.

THE HARE ISLAND EPIDEMIC.

The epidemic of typhus fever which was reported to prevail to an alarming extent has, on investigation, proved to be less extensive than was at first supposed. There are twenty-four cases of typhus fever and one doubtful case on the island, which lies about half a mile off the mainland, and is of small size. Only one death has occurred since the outbreak of fever, or a mortality of about 4 per cent., showing that the disease must be of a mild character. The habitations of the islanders are in a most insanitary condition, and of the forty-one houses all are unfit for human habitation. There is also a considerable amount of overcrowding. The water is obtained from wells, to the majority of which the cattle have access. A guardian of the Skibbereen Union has given notice that a medical officer should be required to reside in the district; the difficulty, however, will be to find any medical practitioner who will consent to accept the appointment.

At the recent examinations for the First Professional of the Royal College of Surgeons, exactly 50 per cent. of the candidates who entered were rejected

A sum of nearly £300 has already been subscribed for the testimonial in memory of the late Dr. Eames of Cork.

Dublin, August 10th.

Obituary.

THOMAS H. PURDON, M.B. DUB., F.R.C.S.I.

IT is with sincere regret that we have to announce the death of another of the older medical practitioners of Belfast, Mr. Thomas H. Purdon, which took place at his residence in Wellington-place on Friday, the 6th instant, at the advanced age of eighty-one. The deceased gentleman, who was the principal representative of an old Huguenot family which settled in Ireland in the reign of Queen Elizabeth, was born in Belfast in 1805, his father being a medical man, Dr. Henry Purdon, Staff Surgeon. After spending some time at the Armagh Royal School, Mr. Purdon entered Trinity College at the early age of thirteen, a sufficient evidence of his precocity, and after a distinguished College course he took the degrees of M.B. and M.A. in 1828; but previous to this, in 1821, he was elected a Fellow of the Irish College of Surgeons. He also studied for a time at Edinburgh. While he was attending in Dublin at the University he was prosector and demonstrator for a well-known man, Dr. Harrison.

Mr. Purdon commenced practice in Belfast in 1828, although from the age of sixteen he had been engaged as assistant in some of the local dispensaries. He soon obtained a large and high-class practice, and enjoyed the complete confidence of the aristocracy of the neighbourhood — a confidence which he retained for upwards of half a century. During the long period in which he was engaged in active practice (sixty years) Mr. Purdon held numerous medical appointments. He was formerly senior surgeon to the Royal Hospital, and latterly consulting surgeon. He was consulting physician to the Belfast Hospital for Consumption, and consulting surgeon to the Ophthalmic Hospital. He was for a time medical officer to the County Antrim Prison, to the Deaf and Dumb Institution, and to the Infirmary and Poorhouse. He was permanent President of the Belfast Branch of the Royal Medical Benevolent Fund Society of Ireland. He was a prominent and highly respected member of the Church of Ireland, and, in recognition of his eminence as a Churchman, and his spotless life, he was ordained as a lay reader by the present Lord Primate of Ireland. Mr. Purdon took great interest in everything pertaining to his native town, and about twenty-six years ago he was a member of the Town Council. He belonged to a medical family *par excellence*.

His grandfather, father, and two brothers were doctors, he had one son in the profession, and at present three of his nephews are in practice. The deceased was an able surgeon, and a skilful and much-trusted physician. It is said he performed the first case of tracheotomy in Ireland, the subject of which lived for thirty-six years afterwards. He was a great reader, and amassed a fine collection of medical books. He was also at times a contributor to the *Dublin Medical Journal* and to the *Medical Press*, but it is probable that had his practice not been so large he would have written more. Few medical men have occupied a more respected and honourable position than the late Thomas Henry Purdon. By his numerous patients he was beloved as much for his extreme kindness as for his skilful treatment of their maladies, while by his professional brethren he was respected on account of his abilities, his ripe experience, and especially on account of his thoroughly honourable and upright professional conduct. He was by birth, education, ability, and high personal character an honour to the medical profession.

THE SERVICES.

SURGEON H. S. PARKER, Medical Staff, having rejoined from the three months' privilege leave of absence granted to him to visit Rachenir, has returned to the duties of Staff Surgeon, Medical charge of the Ordnance Department, and of the Lock Hospital at Ferozepore.

WAR OFFICE.—Army Medical Staff: Brigade Surgeon Alexander Frederick Bradshaw to be Deputy Surgeon-General, vice J. J. Thompson, retired.

ADMIRALTY.—The following appointments have been made:—Fleet Surgeon Godfrey, to the *Rupert;* Fleet Surgeon W. B. Fletcher, to Sheerness Yard; Fleet Surgeon J. S. Dolby, to the *Crocodile;* Surgeon J. Porter, to the Bermuda Hospital; Surgeon W. R. Young to the *Impregnable;* and Staff Surgeon W. E. Bennett, to the *Pylades.*

YEOMANRY CAVALRY.—Westmoreland and Cumberland: Surgeon and Honorary Surgeon-Major Joseph Wickham, M.D., resigns his commission.

ARTILLERY VOLUNTEERS.—1st Orkney: Acting Surgeon John Gibson resigns his appointment.

RIFLE VOLUNTEERS.—6th Lancashire (1st Manchester): Leslie Hudson Jones, Gent., M.D., to be Surgeon.

Medical News.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS OF EDINBURGH AND FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—The following candidates at the July sittings of the Examiners, held in Glasgow, passed the examinations for the triple qualification conferred by the three Scottish medical corporations, and were admitted Licentiates:—

J. M'Clymont, Edward Ball, Ewen Whitwell, Henry Johnson, Archibald M'Arthur, John C. Davidson, John K. Jones, Alfred J. Harwood, and A. C. Milne, of the Glasgow Medical School; Alice Jane S. Ker, of the Edinburgh School and the London Medical College for Women; H. W. Cross, of the Newcastle-on-Tyne School; A. H. Hoffman, of the Birmingham School; F. H. Gaunson, of Melbourne University and the Edinburgh School; J. F. Chapman and Alfred W. Rinder, of Melbourne University; W. C. Halpin, of the Dublin School; Joseph de Souza and F. V. A. de Souza, of the Grant Medical College, Bombay; Francis D. Robertson, M.D., M'Gill College, Montreal.

SOCIETY OF APOTHECARIES.—The following gentlemen passed their examination in the Science and Practice of Medicine, Surgery, and Midwifery, and received certificates to practise, on Thursday, the 5th inst.:—

Dutt, Aaron Chaunder, 200, St. Paul's-road, Highbury, N.
Tomlinson, William Henry, 13, Craig-street, Devonshire-street, Manchester.

At the recent examination for the Prizes in Botany given annually by the Society of Apothecaries, the successful candidates were:—

Boyce, Robert W., of University College, the Gold Medal.
Hall, Frederick William, of Guy's Hospital, the Silver Medal and Books.

VACCINATION GRANT.—Dr. Dearden, Church, has received the grant for efficient vaccination in his district sixth time).

ON the 4th inst. a bazaar in aid of the funds of the Royal Surrey County Hospital was opened at Guildford by Prince Albert Victor.

AN open-air concert of sacred music was given at Rochdale on the 8th inst., in aid of the funds of the local infirmary, the proceeds amounting to £124.

PRESENTATION.—On the fifth inst. the members of the Redcliffe and Totterdown Dispensary presented Mr. H. Mc Quade, B.A., M.B., B. Ch. Dub., with a dining-room clock as a token of their esteem and as a recognition of his recent marriage.

THE VATICAN AND CREMATION.—The Roman Holy Office has issued a decree forbidding Roman Catholics to belong to cremation societies, and the practice of cremation is stigmatised as *detestobilem abusum corpora humana cremandi.*

WATFORD DISTRICT COTTAGE HOSPITAL. — The ceremony of opening this hospital, recently erected in the Vicarage-road, was performed on the fifth inst. by the Countess of Clarendon. It affords accommodation for nine patients. The cost of the building and site is about £2200.

INTERNATIONAL ASSOCIATION OF SURGICAL AND ORTHOPÆDIC INSTRUMENT MAKERS.—The fourth meeting of this association will be held at 12, Dorotheenstrasse, Berlin, on Tuesday, September 14th, at 6 P.M. Intending members of any nationality are invited to attend. Mr. Krohne, of 8, Duke-street, Manchester-square, London, W., is the secretary.

ROYAL UNIVERSITY OF IRELAND.—The following exhibitions and honours have been awarded:—First Examination in Medicine:—Exhibitions: First Class (£30), John McNamara; Second Class (£15), Jeremiah Ambrose. Honours: First Class, John McNamara; Second Class, Jeremiah Ambrose, John E. W. Cruise James R. Steen, Walter V. A. Raleigh.

MUNICIPAL LIBERALITY.—At its sitting of July 31st, the Municipal Council of Paris voted a credit of 289,765 francs (£11,590) for the construction of a new surgical department at the Hôpital Cochin, to replace the wooden huts erected during the siege. It is intended to provide for all the requirements of modern surgery, with laboratory, means of isolation, &c.

THE Council of the Medical Defence Union has determined to memorialise the Local Government Board on behalf of Mr. Simpson, who it will be remembered was requested by the Local Government Board to resign his post as medical officer to the Birmingham Workhouse on account of an outbreak of puerperal fever in that institution, which it was alleged that Mr. Simpson by his recklessness had caused.

HOSPITAL SATURDAY FUND.—At a meeting of the board of delegates of this fund held on the 7th inst., it was reported that, notwithstanding the very inclement weather on the occasion of last Hospital Saturday, the 17th ult., the falling-off in the collection had not proved as large as had been anticipated. The diminution amounted to nearly £500. The total of the collection, so far as it was yet ascertainable, was £4039.

APOTHECARIES' HALL OF IRELAND.—The following have been elected office-bearers for the ensuing year:—Governor: Edward J. O'Neill. Deputy-Governor: George Wyse. Court of Directors and Examiners: Edward H. Bolland, Thomas Collins, John Evans, Arthur Harvey, Charles Holmes, Charles H. Leet, Robert Montgomery, Charles F. Moore, Henry P. Nolan, Richard O'Flaherty, Sir George B. Owens, J.P., John Ryan, and James Shaw. Representative on the General Medical Council: Thomas Collins. Secretary: Robert Montgomery.

THE UNIVERSITY OF LONDON.—At the recent preliminary Scientific (M.B.) Examination, 58 candidates passed the entire examination—viz., 25 in the first division and 33 in the second. Thirty-four candidates satisfied the examiners in two subjects of the examination, and 31 in one subject. At the Intermediate Examination in Medicine, 32 passed the entire examination—52 in the first and 30 in the second division. In all subjects, excluding Physiology, 12 passed—10 in the first and 2 in the second division. In Physiology only, 15 passed, the names of 8 appearing in the first division. In the Examination for

Honours at the Intermediate Science and Preliminary Scientific (M.B.) conjointly, the following are the numbers of successful candidates:—Inorganic Chemistry, first class 5, second class 5, and third class 6; Experimental Physics, 2, 3, 3, respectively. In Botany, one candidate obtained a first and 2 candidates a third class. In Zoology, the names of three candidates appear in the first class, 4 in the second, and 3 in the third.

AN epidemic of measles amongst the children in the Driffield Workhouse was reported to the Local Board of Guardians on the 5th inst. The disease is also prevalent in the town.

AT a recent meeting of the Paris Municipal Council the concession of land for the erection of a Pasteur Institute was extended from thirty to ninety-nine years. A vote, expressing unqualified admiration of M. Pasteur, was also carried.

MEDICO-LEGAL LABORATORIES IN SPAIN. — The Spanish Ministry of Justice has arranged for the establishment in Madrid, Barcelona, and Seville, of laboratories of forensic medicine. After the middle of September, analyses which may be ordered by magistrates will be conducted in the new institutions—a provision enabling experts nominated in the interests of accused persons to be present during the performance of such analyses.

DEATH FROM ETHER.—An inquest was held on the 6th inst., by Dr. Diplock, on the body of Mrs. Wesselhoeft, the wife of an American physician. From the evidence it appeared that the deceased had suffered from asthma, for the relief of which she was supplied with other. A pint bottle two-thirds full of the drug was found by the bedside, and the atmosphere of the room was charged with the vapour of ether. The jury returned a verdict in accordance with the medical evidence, and expressed the opinion that it was unwise to have allowed the deceased to have so much ether at her command.

PARKES' MEMORIAL PRIZE ESSAY.—Six essays were sent in on Dec. 31st, 1885, on the following subject:—"The Prevention of Disease among Troops during Military Operations in Tropical and Subtropical Climates." The following gentlemen consented to act as Assessors at the request of the Committee:—Surgeon-General W. C. Maclean, C.B.; Deputy Surgeon-General J. A. Marston, M.D.; Hon. Deputy Surgeon-General H. L. Veale, M.D. After careful consideration of the essays, the Assessors unanimously adjudged the prize to Dr. Andrew Duncan, F.R.C.S., Indian Medical Service, who entered the Medical Service on Sept. 30th, 1878. The prize consists of a gold medal of the value of 15 guineas, and £100 in money—it is awarded triennially; the subject for the next essay being "The Etiology and Prevention of Yellow Fever, to be illustrated so far as possible from the personal experience of the author." Essays to be sent in to the Director-General, Medical Staff, War Office, London, S.W., on or before the 31st Dec., 1888. The competition is open to all executive medical officers on full pay of the Royal Navy, Army, and Indian Medical Departments.

ARSON BY MEANS OF PHOSPHORUS.—At the last Manchester Assizes in July, a solicitor and a builder were sentenced, the former to ten and the latter to seven years' imprisonment, for arson. In December last, they took a shop in Hulme, fitting it up as a cigar shop, but not living upon the premises. The stock was valued at about £2 10*s.* and the fixtures were of the thinnest wood, and under the counters were large quantities of shavings. They ensured the stock and fixtures for £950 in April last, and in the night of the 19th of June a fire broke out, and on the arrival of the fire-brigade there were found to be three distinct fires in different parts of the shop and house. The two firemen who first entered were nearly suffocated by a dense white smoke; and applied to Mr. Heslop, Divisional Surgeon, Manchester police force, a day or two after, complaining of a rawness of the throat and chest, very different from anything they had experienced before. On account of what they told, Mr. Heslop burned some phosphorus in their presence, and they at once recognised the smell. Some phosphorus was then placed in some shavings, and it ignited spontaneously in about eight or ten minutes, and in sawdust in about twenty minutes. The gas-pipes had been cut, and the ends joined with indiarubber tubing. The defence was that there was no evidence that the prisoners were the men who set fire to the place.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

JACK, JOHN S., M.B., C.M.Glas., has been appointed Medical Officer for the Rothbury East District of the Rothbury Union.

OLDMAN, CHARLES E., M.D.Cantab., M.R.C.S., has been appointed Medical Officer for the Workhouse and the Western District of the Godstone Union.

PEARCE, FRANCIS D., M.R.C.S., L.S.A., has been appointed Medical Officer for the South District of the Kingsbridge Union.

PROWSE, W., M.R.C.S., L.S.A., has been appointed Medical Officer for the Hutton District of the Axbridge Union.

WHITTINGTON, T., L.F.P.S.Glas., L.R.C.P.Ed., has been appointed Medical Officer for the Prestwich District of the Prestwich Union.

Births, Marriages, and Deaths.

BIRTHS.

DRURY.—On the 6th inst., at Lingmoor, Dean-park, Bournemouth, the wife of W. V. Drury, M.D., of a daughter.

GRAMSHAW.—On the 3rd inst., at Walton-on-Naze, the wife of Henry Gramshaw, M.D., of a daughter.

LLOYD.—On the 8th inst., at Ty'nycoed, Barmouth, the wife of H. J. Lloyd, L.R.C.P., &c., of a son.

WILLIAMS.—On the 6th inst., at The Grange, Grinshill, near Shrewsbury, the wife of Clarence Williams, M.R.C.P., of a daughter.

MARRIAGES.

DAVIS—MALTBY.—On the 4th inst., at Old Basford Parish Church, Frederick Howard Davis, L.F.P.S., L.S.A., of The Grove, Dawley, Salop, to Maud Mary Maltby, daughter of Dr. Maltby, of Old Basford, Notts.

DE'ATH—ZIMMERMANN.—On the 5th inst., at St. Stephen's Church, Castle-hill, Ealing, by the Rev. B. Seymour Tuphohme, Vicar, assisted by the Rev. John Chubb Ford, George Hauby De'Ath, L.R.C.P. Lond., M.R.C.S.Eng., youngest son of the late Robert De'Ath, of Buckingham, to Margaret Fair, youngest daughter of Edward Zimmermann, of 5, Cleveland-gardens, Castle-hill, Ealing, formerly of Buenos Ayres.

GORDON—GARLAND.—On the 4th inst., at St. Michael's, Croydon, George A. S. Gordon, M.A., L.R.C.P.Ed., L.R.C.S.Ed., to Emily, third daughter of Captain Augustus Henry Garland, of Sydney Lodge, Croydon.

GREENWOOD—JENKINSON.—On the 5th inst., at St. Paul's, Clapham, Cecil Danforth Greenwood, M.R.C.S., to Annie Beatrice, daughter of Alfred Jenkinson, of Clapham.

HALL—MORGAN.—On the 4th inst., at St. Mary's Church, Dilwyn, T. Lambert Hall, M.R.C.S., of Great House, Dilwyn, to Edith Mabel, third daughter of the Rev. T. Morgan, M.A., Vicar of Dilwyn, Herefordshire.

HANLY—MATTS.—On the 5th inst., at the Church of the Holy Cross, Leicester, by the Rev. F. Procter Prior, assisted by the Rev. F. Gabriel Whitacre, Dr. T. F. Hanly, of Newtown Desford, second son of R. Hanly, Esq., of Brighton, to Hannah Elizabeth Hooley, only daughter of the late Joseph Henley Matts, Esq., of Cropstone, Leicestershire.

KEETLEY—LONG.—On the 5th inst., at St. Mary's, Clapham-park-road, by the Rev. Richards Crofts, Charles B. Keetley, F.R.C.S., of 10, George-street, Hanover-square, W., to Anna M., daughter of the late Henry Holmes Long, Esq., H.E.I.C.S.

MACDONOGH—HANCOCK.—On the 10th inst., at All Saints', Isleworth, William Frederic MacDonogh, L.R.C.P., M.R.C.S., to Thérèse Uziell, eldest daughter of Thomas Webster Hancock, Esq., of Treskelly, St. Margaret's, S.W.

MACKINNON—MACPHAIL.—On the 5th inst., at the Free Church, Manse Kilmuir, Isle of Skye, by the Rev. J. Calder Macphail, uncle of the bride, Francis Irvine MacKinnon, M.B.Edin., M.R.C.S., Medical Missionary, Damascus, to Lydia Jessie, second daughter of the Rev. John S. Macphail.

PENNY—PINDER.—On the 5th inst., at St. Matthew's, Denmark-hill, by the Rev. Stephen Penny, M.A., brother of the bridegroom, assisted by the Rev. H. Weston Wright, Edmund J. Penny, Esq., M.R.C.S., of Berkhampsted, Herts, to Annie Sophia Devall, daughter of Dr. and Mrs. Pinder, of Camberwell-green.

ROBSON—BALLARD.—On the 4th inst., at the Parish Church of Preston, Sussex, W. W. Constable Robson, M.R.C.S., of Walkeringham, Notts, to Rebecca, third daughter of Richard Ballard, of Patcham, Sussex.

DEATHS.

ARMSTRONG.—On the 5th inst., at Brampton (suddenly), William Armstrong, Surgeon, J.P. for the County of Cumberland, aged 74.

COVENEY.—On June 25th, John Coveney, M.R.C.S. (of phthisis), aged 25.

FOWLER.—On the 7th inst., at Hampstead, Robert Fowler, M.D., of Old Burlington-street, and Bishopsgate-street Without, aged 58.

MADDEN.—On the 8th inst., at Northwich-terrace, Maida-hill, Christopher J. Madden, M.D., aged 81.

MANN.—On the 4th inst., at Kingsdown Villas, Wandsworth-common, Robert James Mann, M.D., F.R.C.S., aged 89.

PLAYFAIR.—On the 6th inst., at Fishery House, Boxmoor (suddenly), Charles Edward Playfair, Staff-Surgeon, R.N., retired.

N.B.—*A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.*

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

We cannot undertake to return MSS. not used.

"A HOSPITAL ROMANCE."

THE *Leisure Hour* for the present month contains an affecting account of an incident in London hospital life, which, while evidently not overdrawn, is strikingly descriptive of the interest taken by the officials of medical charities in the well-being of patients placed under their charge. The "romance" should serve to enhance the interest of the public, which will bear a little quickening, in the beneficent institutions whose "praise" recently was "in all the churches."

Thirty.—The question is a legal one, the answer to which depends on the agreement as to costs beforehand.

Dr. Julius Büdinger.—We will consider the suggestion.

THE "PENDJEH SORE."

To the Editor of THE LANCET.

SIR,—In your issue of April 10th, p. 703, an account of the "Pendjeh Sore" is given, from the *Vrach*, by Dr. Suski, and in your issue of June 12th, p. 1148, Surgeon Pierson points out the identity of this disease with Oriental sore known under many names, as "Delhi boil," "Scinde boil," "frontier sore," &c. A full account of the distribution will be found in Hirsch's Geographical Pathology, vol. ii. (New Sydenham Society). I pointed out this identity in an Indian journal early in May, where I also added that the account of the bacillus and every statement given in your abstract, and supposed to be original, will be found in my article on this subject in the *Practitioner* of last January.

I am, Sir, yours obediently,

Burmah Field Force, July 11th, 1886. J. HICKMAN, Med. Staff.

B.—The Royal Benevolent College answers to our correspondent's first question. There is a Branch Medical Council for Scotland; address—4, Lindsay-place, George IV. Bridge, Edinburgh.

A MONSTER CHILD.

To the Editor of THE LANCET.

SIR,—Here is a nut for physiologists to crack. A thin little woman gave birth to a male child sixteen months ago, at the village of West Camel, Somerset. When born the infant was of ordinary size in every way; it now weighs and measures as follows: Length, 36 in.; circumference round abdomen 33 in., chest 30 in., thigh 17 in., calf 11½ in., neck 10½ in., arm 10 in., and face 17 in. It is perfectly impossible for anyone to conceive its extraordinary appearance without seeing it. Its weight is 4 st. 8 lb. I may further add that the father is a man of ordinary size. The infant seems very intelligent and happy, but on account of its enormous weight it cannot be lifted without expressing pain.

I am, Sir, yours faithfully,

Sherborne, July, 1886. NATHL. EDWARD DAVIES.

THE NEW SOLICITOR-GENERAL ON THE BARTLETT CASE.

MR. EDWARD CLARKE, Q.C., contributes the following preface to a complete and revised report of the Bartlett poisoning case which has lately been issued by Messrs. Stevens and Haynes. The preface is dated, "5, Essex-court, Temple, July, 1886":—

"The case of which a complete and corrected report will be found in this volume attracted so much public attention, and had in it so many elements of enduring interest, that I think it desirable that it should be recorded in a permanent and convenient form. The very large correspondence which came to me during the progress of the case from members of the medical profession showed that the questions which had to be discussed were felt to be of great importance in the study of medical jurisprudence; and I have never known a case, or at all events not more than one, which had in itself so strong a dramatic interest. The strange relations between the prisoner and the husband, with whose murder she was charged, the yet more strange relations between her and the man who in the first instance was included in the accusation, together with the exceptional circumstances of his acquittal and his immediate appearance in the witness-box, fully explain the great public interest which existed during the trial, and which culminated in the very remarkable scene which followed its conclusion. It was at my request that my friend, Mr. Edward Beal—from whom, as well as from Mr. Mead, I received during the case the most diligent and admirable assistance—has undertaken the duty, which he was specially qualified to perform, of preparing the volume for the press, and I am greatly obliged to him for the care which he has given to his task. Mr. Justice Wills has been good enough to revise the report of his summing-up, and Sir Charles Russell has kindly performed the same service in respect of his opening speech and reply. Mr. Sidney Plowman, of St. Thomas's Hospital, has supervised the medical references in the report, and thereby added to the obligation under which all concerned in the defence already stood for his assistance during the case. I trust that the volume may be found useful to all students of the administration of the law."

A. B. C.—Illustrated Lectures on Ambulance Work, by R. Lawton Roberts, M.D., published by Lewis, Gower-street, 1883.

THE "EXCELSIOR" PATENT COMBINATION GIG-PHAETON.

To the Editor of THE LANCET.

SIR,—Messrs. Cliff and Sons, of Wellington, Salop, exhibited at the "Inventories" last year a pony carriage which could be converted at will from a four-wheeler to a two-wheeler. The gold medal of the exhibition was awarded to them for this carriage as the most ingenious improvement in carriage-building that was exhibited. At my request they have adapted their invention to another class of vehicle—one which may be described as a gig-phaeton. The idea in my mind was to provide a carriage which should serve several different purposes needed especially by country doctors. In the winter, when roads are heavy, the prime requisite of an effective carriage for a country practitioner is easy draught. A two-wheeler, as compared with a four-wheeler, must always have the advantage in this respect, particularly in hilly districts. The great drawback of two-wheelers is the want of accommodation. This patent combination carriage makes a nice-looking, easily-worked gig for winter work, and an equally good-looking phaeton for summer weather, capable of bringing a friend and luggage from the railway station, or of accommodating four or five passengers in case of need for a picnic or dinner party. With hood and apron there is effective shelter in rainy weather. The four-wheeler has a full lock in turning, and the two-wheeler is balanced by means of a screw slide, and has therefore an easy motion. The distinctive advantages of the combination are (1) that the purchaser gets two carriages for the price of one—viz., from £52 without hood; (2) that one tax is paid for the two carriages; and (3) that only one coachhouse is needed for the two carriages. I do not know of any other carriage combining in one all these advantages.

I am, Sir, yours faithfully,

Southborough, Aug. 10th, 1886. E. PAGET THURSTAN, M.D.

A USEFUL PLANT.

DR. BRANDES, a Hanoverian physician, has recently demonstrated in a German contemporary the valuable properties of the anacharis alsinastrum, a water-plant which has hitherto been considered as an unmitigated nuisance, choking up rivers, and altogether useless. Dr. Brandes has remarked that in the district where he lives, and where malaria and diarrhœa yearly appeared in a sporadic or epidemic form, those diseases have gradually decreased since the anacharis alsinastrum began to infest the neighbouring rivers and marshes, and for four years have totally disappeared. He therefore proposes that the plant, which came originally from Canada, should be planted in marshy districts, with the view of checking malaria; and the experiment, in view of the evidence adduced in the article under notice, is certainly deserving of consideration.

Mr. Wm. Hedley had better study medicine at home first. The *Journal of the American Medical Association* is published in Chicago; the *Medical Record* in New York. Either of these journals might serve our correspondent's purpose.

Mr. Hawkins-Ambler.—Yes, in an early number.

THE MISSION TO DEEP SEA FISHERMEN.

THE useful work of the Mission to Deep Sea Fishermen is, we are glad to notice, receiving further recognition and support. An anonymous donor has recently contributed £2300 to cover the entire cost of building and equipping a seventh medical mission vessel to cruise with the North Sea trawling fleet. The medical and surgical work done on board these vessels is most important. The log of the vessel just arrived at Great Yarmouth after a two months' cruise with the Columbia fleet shows that no fewer than 200 cases have been treated in the dispensary during the voyage. One naturally asks what would these patients have done had there been no mission ship in the fleet. The more trivial cases would have had to endure until the return to port, whilst the serious ones would have been shipped off to London by the steam trawlers, which means being transferred in a small open boat from smack to steamer, and two days of suffering before the hospital can be reached. It is to be hoped that funds may be speedily forthcoming to enable the Mission to place a vessel with every fleet in the North Sea.

B. ought to make a claim if the executors show no sign of carrying out the wishes of A.

"THE OVERCROWDING OF THE PROFESSION."

To the Editor of THE LANCET.

SIR,—Your correspondent, "Felix Holt," very pertinently inquires in your issue of July 3rd, p. 43, "What may we expect the condition of the profession to be in half a century if some steps are not taken to prevent overcrowding?" I think I may say that this state of affairs is now under consideration in Canada—in the older provinces, at any rate—and those in authority are endeavouring to find a remedy for it. The principal steps to this end have been, so far, the raising of the standard of both matriculation and primary and final examinations, increasing the fees, and in the case of one university the term of study has been lengthened. The fact remains, nevertheless, that some schools in Canada, and many in the United States, are far too lenient as regards both the course of study and examinations. In this country there are but solitary cases of medical partnerships, and the assistant system is unknown. Consequently, every practitioner has to make a practice for himself. In reply to the concluding inquiry in your correspondent's letter, I may state that a degree from a British university gives the same privilege as the licence of the Royal Colleges. A person not holding some such qualification would have to pass an examination in Ontario or Quebec only if he intends to practise in those provinces.

I am, Sir, yours faithfully,

Montreal, July 16th, 1886. L.C.P.S. QUE.

"THE METROPOLITAN DISPENSARY," COMMERCIAL-ROAD.

A CORRESPONDENT sends us one of the cards of this dispensary, distributed promiscuously among the patients of other practitioners and dispensaries, with the signature of the resident physician. Our correspondent expresses his strong disapproval of such a system as an advertising one; and we agree with him.

C. L.—No vaccination certificates from Ireland are accepted in England in place of English certificates. The only places outside England where certificates can be obtained are Edinburgh and Glasgow, and there the vaccination stations are under special inspection.

"THE USE OF COCAINE IN CIRCUMCISION."

To the Editor of THE LANCET.

SIR,—As a commentary upon the cases lately reported under this heading, will you permit me to ask the question, Is circumcision (for congenital phimosis) a justifiable operation? We know that fatal results have followed this procedure; and besides the risk, however small that may be, the parents, when not of the Hebrew persuasion, usually dislike the idea of their child "being made into a little Jew."

In the case of my own little boy and of several others, I have, under ether, introduced under the prepuce the closed blades of a pair of dressing forceps, and have then widely separated these. It is surprising how easily the prepuce can then be retracted behind the glans, which must be thoroughly exposed and cleaned. For a few days the foreskin must be drawn back. If thoroughly loosened on the first occasion there will be no difficulty whatever. Probably all this could be efficiently done under cocaine. At any rate, the success of the little manœuvre makes me urge its substitution for the cutting operation.

I am, Sir, yours faithfully,

Norfolk-terrace, W., Aug. 3rd, 1886. HERBERT SNOW.

COLOUR-BLINDNESS.

DR. WORMS, having examined 11,175 persons in respect of colour-blindness, has communicated his results to the French Academy of Medicine. Of the above number he found two only incapable of distinguishing one colour from another, three were blind for red and six for green, eighteen could not distinguish green from red, fifteen saw no difference between green and blue or grey, and fifty-two had a peculiar weakness in colour vision in general.

Mr. William Habgood.—Only graduates of universities are entitled to the prefix.

HEIGHT AND WEIGHT.

DR. BROCA, the eminent French anthropologist, is the author of a formula relative to the height and weight of the human body. It is that the body should weigh as many kilogrammes as it measures in centimetres, after deduction of the first metre. Thus a man measuring one metre eighty centimetres should weigh eighty kilos. Should his weight be more or less, he is too stout or too thin. As men grow older they lose their weight, but as a compensation they diminish in height also.

Justitia.—The insertion of the letter would probably lead to a discussion of a painful nature without corresponding benefit. Moreover, the matter is scarcely within our province.

"LEAD IN TINNED PROVISIONS."

To the Editor of THE LANCET.

SIR,—I notice in your valued journal the remarks of Dr. Rabcherski of St. Petersburg as to lead poisoning in connexion with preserved provisions. I am taking the liberty of sending you a tin invented by me during the last two years for the purpose of overcoming the difficulties spoken of by your correspondent. It is struck out of solid tin plate, and reduces to a minimum the danger of lead and other poisoning. In the first place, only tin plates of the very best quality can be used—that is, plates coated with pure block tin. The use of inferior plates coated with lead would result in too large a percentage of burst tins in the process of manufacture, as the strain is very great; therefore firms who prepare cheap goods cannot avail themselves of this method. To such perfection has this machine been brought that it strikes out 10,000 tins per day, with an average of not more than three damaged ones. The meat (or other contents) rests on the part of the tin struck out, and the top is soldered externally with solder composed of seventy parts of pure block tin and thirty parts of lead. This mixture is used for the sake of purity, also because it accelerates the work, which is of importance, as the quicker the preserving process is accomplished the better the results.

Trusting you will give place for these remarks in your columns,

I am, Sir, your obedient servant,

Leadenhall-street, E.C., Aug. 7th, 1886. J. MOIR CLARK.

"SUICIDE FROM DYSPEPSIA."

IN an annotation last week headed as above, we asked if the sufferer from dyspepsia in the case referred to had been under treatment of any kind. Mr. Ronse, the husband of the deceased, in a letter to us, replies that "she was, and had been for years, and was visited only the morning before the sad event by her medical attendant."

An Enquirer (Cleckheaton).—The suggestion is not new. The connexion between cause and effect, supposing such to exist in the matter referred to, is not very clear.

A CENTENARIAN.

To the Editor of THE LANCET.

SIR,—The following case of longevity may interest some of your readers.

Joseph Gathercole died at the Thingoe Union last week at the advanced age of 104 years and eight months. The accuracy of this age may be ascertained from the fact that he has been, on and off, an inmate of the union since it was built in 1836, and that at the time of his admission he was supposed to be about fifty-five years of age. Up to a few months of his death he was hale and hearty, and able to get downstairs and walk about.—I am, Sir, yours truly,

CHARLES SCOTT KILNER, M.B.,
Medical Officer of the Thingoe Union Workhouse.

Bury St. Edmunds.

DEAF-MUTISM IN SPAIN.

ACCORDING to Señor Don J. Lopez Navalon, principal of the National College for Deaf-mutes in Madrid, the number of persons afflicted with deaf-mutism in Spain is more than 10,000. For these there are, besides the Madrid College, which is supported by the State, only four other institutions in the provinces, and these are all supported and managed by private enterprise.

William Penn.—The question is entirely subject to the action of the General Medical Council in the matter of the recognition of foreign degrees.

CANCER OF RECTUM; COLOTOMY.

To the Editor of THE LANCET.

SIR,—I have a patient upon whom I performed colotomy a fortnight ago whose case is interesting from two points. In the first place, she is only twenty-three years of age, and has such extensive cancer of the rectum as to have suffered complete obstruction of the bowels for three weeks. Secondly, the mode of death promises to be unusual. She was progressing rapidly towards recovery when, on the twelfth day after the operation, violent hæmorrhage came on, and has recurred to an alarming extent from time to time since. This bleeding evidently comes from the lower part of the bowel and from the cancerous mass itself, and will probably be the immediate cause of death.

I am, Sir, yours faithfully,

JOHN ALCOCK,
Surgeon, North Staffs. Infirmary.

Burslem, Aug. 9th, 1886.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Sir Andrew Clark, London; Dr. Unna, Hamburg; Dr. Jose P. Rego Filho, Buenos Ayres; Dr. Herbert Snow, London; Dr. Rüdinger, Vienna; Dr. F. Kammerer, Berlin; Mr. V. Horsley, London; Mr. Reginald Harrison, Liverpool; Dr. R. D'O. Stephenson, London; Mr. Bruce Douglas, Lucerne; Mr. G. Padley, Swansea; Mr. G. H. Browne, Brynmawr; Mr. J. M. Clark, London; Messrs. Duncan, Flockhart, and Co., Edinburgh; Mr. W. Young, London; Mr. Grattan, Cork; Mr. J. Alcock, Bursiem; Mr. J. W. Wood, Liverpool; Messrs. Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed.

Advertisements are now received at all Messrs. W. H. Smith and Son's Railway Bookstalls throughout the United Kingdom and all other Advertising Agents.

Agent for the Advertising Department in France—J. ASTIER, 66, Rue Caumartin, Paris.

Clinical Lecture
ON A
CASE OF HAMMERMAN'S CRAMP.

By G. V. POORE, M.D., F.R.C.P.,
PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL.

GENTLEMEN,—The case which I wish to bring to your notice to-day is one belonging to the class of "professional ailments" in which the constant repetition of the same movement begets an inability to perform that movement—a movement which often constitutes the profession of the sufferer, and is his sole source of income. These troubles are very serious for the patient, and, once established, they prove a source of mental anxiety and worry which can hardly be exceeded. On this account they are deserving of a very careful study, albeit that we know nothing for certain of their pathology, because these troubles are never fatal. The commonest of this class of diseases is "writer's cramp," of which I have seen about two hundred cases. Failure of professional movements other than writing is infinitely rare, but I have had occasion to see pianists who cannot play the piano; violinists who have lost the power to manipulate the strings with the left hand, or hold the bow in the right hand; a violoncello player who had lost the power to "make the nut" with the phalangeal joint of the left thumb; a compositor who could no longer hold the "stick" in his left hand; a tailor who could not sew; a pickle-jar-tyer who had lost the power of grasping the top of the jar with his left hand; a watchmaker who could not hold his watchmaker's lens in his eye; a packing-case-maker who could not use his saw; a bricklayer who could not use the trowel; and lastly a nailmaker (our patient of to-day) who cannot wield his hammer.

Other observers have described similar affections in telegraphists (I have never seen a case of telegraphist's cramp), ballet dancers who perform the "pas des pointes" on the tips of their toes, milkers, and fencing masters; and Professor Dieulafoy once told me that he had seen a cellarman from Rheims who had lost the power of giving a slight rotary movement to a champagne bottle, a movement which he was called upon to exercise all day and every day.

The investigation of these cases requires great care. Search must be made methodically and diligently for peripheral evidence of mischief, and we must bear in mind that no two cases are alike in all respects, and that since no two persons probably perform the same professional act in precisely the same way, so the mode of break-down will be found to differ immensely.

Careful examination of these cases has shown me that the break-down is generally most evident in those muscles which are subjected to prolonged strain rather than in those in which the periods of contraction and relaxation are more equally divided. Thus in writer's cramp it is the muscles of pen-prehension rather than those of pen-movement which are liable to fail. In the comparatively few cases of pianist's cramp which I have seen the extensors of the wrist and the near phalanges have been at fault. In the packing-case maker who could not wield his saw the chief trouble seemed to be in the supra-spinatus muscle, which during the act of sawing is subjected to prolonged strain. "Dancer's cramps" would probably be unknown if rhythmical movements, such as constitute dancing proper, alone were executed. It occurs only in those who abandon the rhythm which is the very essence of dancing for the performance of an acrobatic "tour de force."

The following history of our patient is summarised from that very excellent record which has been made by Mr. L. Barnett, house-physician.

J. M——, aged twenty-five, nailmaker, admitted Feb. 2nd, 1886. He is a piece worker—i.e., the more nails he can make the more money he will earn. He has worked from 7 A.M. to 7 P.M., with about forty minutes' interval for meals. He has worked in a hot place in-doors, and has been in the habit of taking three or four pints of beer per diem with occasional spirits. There is nothing in the family history of definite import; but the death of his parents at fifty-four and fifty, and the loss of eleven brothers and sisters (out of thirteen) in infancy, make it probable that our patient's "constitution" is not very robust. His work consists in forging nails with a moderately light hammer. The iron is seized with pincers in the left hand, placed in position, and then forged into shape by a rapid succession of blows dealt by the hammer in the right hand. The onset of his trouble was almost sudden. He states that on Monday, June 8th, 1885, after he had been at work for about two hours, he was seized with an inability to direct the blows with his right hand. The trouble increased during the ensuing three hours, when, in consequence of the intense feeling of fatigue, he was obliged to "knock off work" for the day. On June 9th he managed by dint of holding the elbow close to the side to get through his day's work. On June 10th, 11th, 12th, and 13th he worked as well as ever. On the following Monday (June 15th) his trouble returned, but not to the same extent, and he got through his week's work fairly well by holding his elbow close to the side. After this the feeling of loss of aim in the arm recurred every Monday, and gradually wore off during the week, but the period it took to wear off got greater each time. By September the constant pressure of the elbow against the side produced soreness, and when attempts were made to keep the arm against the side the limb jerked, so that further work became impossible, and on Sept. 4th he had to leave it off. The patient states that after this everything he did with his right arm was done clumsily. He was then admitted into the Royal Free Hospital under Dr. Harrington Sainsbury, by whose kindness I first was enabled to see him.

Leaving the Royal Free Hospital, he next went to St. Bartholomew's, and from the latter institution he came here. On admission the "present state" was taken with great care and minuteness by Mr. Barnett. On the chest are a few small scars, the result of burns from sparks; otherwise the skin is normal. The circulatory, respiratory, digestive, and genito-urinary systems present no abnormalities of any kind. The temperature during his stay in hospital was always normal, but the pulse, when recorded, was found to be rather infrequent, being 62 on one occasion and 56 on another.

As regards the nervous system, it is noted that the intelligence was good, that there was no headache, and that the special senses were normal. The third, fourth, fifth, and sixth cranial nerves were apparently normal. The right naso-labial fold was rather less marked than the left; the mouth dropped a little on the right side when at rest and moved a little less vigorously than the left side. The tongue is slightly tremulous when protruded, and the median furrow deviates very slightly to the right side. The right upper limb, if carefully observed, will be noted to be seldom or never quite still. When sitting up with the arms hanging by the side the right arm is the seat of constant slight movements,—elevation, and adduction of the humerus, and flexion of the elbow. When an attempt is made at voluntary movement, the spasmodic action of the muscles of the upper limb is increased. The arm is held fixed to the side, the wrist is extended, the hand supinated and closed. The spasmodic action is seen to extend to the deltoid, trapezius, and pectoral muscles. The right sterno-mastoid is also slightly affected. When an attempt is made to use the hammer, the spasm reaches its maximum, and affects the right arm and shoulder to an extent which makes analysis impossible. It is evident that some of the muscles attached to the scapula are in an abnormal condition. I have followed my invariable plan and have carefully outlined both scapulæ with a blue pencil. By this means we see that the inferior angle of the right scapula is at a higher level than the left, that the distance between the mid-vertebral line and the base of the scapula is 5 in. on the right side and 4¾ in. on the left. The spinal border of the right scapula is somewhat tilted, and stands away from the surface of the back. The mass of the rhomboid muscles is very distinctly larger on the right side than the left. Looking to the lower axillary region, it is evident that the mass of the serratus magnus muscle is distinctly less evident on the right side than on the left. There is nothing wrong with the lower limbs, except that the plantar reflex is more marked on the right side than the left. Sensation is everywhere normal. The muscles were tested electrically. When I first saw this patient at the Royal Free Hospital, with Dr. Sainsbury, the irritability of the right serratus magnus to both forms of

current was distinctly diminished. Now, however, the difference in irritability of the two serrati is scarcely noticeable. The patient is free from pain. After attempts at voluntary use of the arm there is a sense of fatigue and some aching, especially beneath the prominent rhomboid muscles on the right side, but beyond this his condition causes no suffering. *None of the nerve-trunks are in the least tender.* It is very evident that the spasm is not now special to the performance of his professional act of hammering. When he is asked to write he picks up the pen with his left hand and then transfers it to the right, and his attempt to sign his name is interrupted by repeated slight shocks of spasm, and the resulting signature bears evidence of the jerking of the hand. No treatment has been of any service to him. He has previously been in two hospitals without benefit. In this hospital he has had electrical treatment, and in addition he took one-sixteenth of a grain of extract of physostigma from Feb. 6th to the 15th, and twenty minims of paraldehyde three times daily from Feb. 15th to the 21st. He is no better.

There are some points about this patient to which I desire to direct your attention, because they seem to me to place his case in a category different from some of the other professional ailments to which I have alluded. First, as to the mode of onset; it is to be noticed that it was comparatively sudden, and the patient fixes the date absolutely, and he states that before June 8th, 1885, he had no trouble at all, but since then he has never worked satisfactorily. In most other "professional ailments" the onset is gradual, the loss of function increases by scarcely perceptible degrees, and for a patient to be able to fix the exact day of onset is infinitely rare. I took occasion to tell you in my preliminary remarks that these professional ailments most commonly affect movements which necessitate, as in writing, a prolonged contraction of muscles. Now, in hammering it is difficult to say where (if anywhere) this prolonged contraction occurs. It would be most likely to occur in some of the muscles which steady the shoulder, and the permanent slight displacement of the right scapula in the case we are considering rather favours such an idea, but I am unable to say anything more definite.

The act of hammering is probably less automatic than many other acts of a similar kind. The action of the right hand depends to a certain extent upon that of the left, which places the metal in position for being struck. The action of the left hand in selecting and placing in position the nails to be forged is far from being a mere monotonous repetition of the same act, and hence the position of the nail when receiving the blows from the hammer must be to some extent uncertain. Hence it follows that each blow with the hammer involves the taking aim and the exercise of no inconsiderable amount of judgment. The act is as much mental as it is automatic, and both arms and the eyes have to act in harmony for its accomplishment. It seems to me such an act as would be likely to produce a considerable amount of mental worry, which would be redoubled on the first appearance of any failure of accuracy. The repetitions of the act were very numerous, and during the eleven hours of work very many thousand blows with the hammer must have been delivered. Dr. Frank Smith of Sheffield, who published a very able paper on this subject in the *British Medical Journal* of October 31st, 1874, estimated that a penblade forger who suffered similarly to our patient delivered about 28,000 blows per diem, and if we assume that the hammer weighs 3 lb. and is lifted 1 foot for the delivery of each blow, this amounts to 35 foot tons per diem. If we assume that the work of delivering the blow is equal to that of raising the hammer, and if we add to the weight of the hammer the weight of the arm, we must allow that the work done is about 150 foot tons per diem. This is by no means a very excessive day's work.

You will observe that, as I have previously said, the trouble is by no means limited to the act of hammering. It very obviously interferes with the accuracy of all voluntary efforts of the right hand, and, indeed, the spasm is noticeable to some extent when the patient is making no voluntary effort with it. It is, or used to be, stated in text books that in these cases, beyond the professional trouble, there is nothing detectably wrong, and that all movements excepting the professional movement are perfect. I dissent from both these statements; but, nevertheless, the present case differs from the great majority of professional troubles in the very large amount of peripheral evidence of mischief which is present and the rapidity with which the motor trouble has spread, as it were, from the professional act to the involvement of other acts. Indeed, one cannot escape from the belief that the motor trouble is part of a hemiplegia, for added to the disorderly movements of the upper limb, we have evidence of slight failure of the right side of the face and the right half of the tongue, and probably the exaggerated plantar reflex on the right side tells of diminished cerebral control over the right leg. These trifling signs of hemiplegia, added to the fact of comparatively sudden onset, make it highly probable that the lesion, whatever it may be, would be found in the motor area of the cerebral cortex on the left side. In addition, notwithstanding that I can find no defect of intelligence of any definite kind, I confess that there is something vacuous in the expression of his face, which, added to a certain listlessness of manner and utterance, leaves upon me the impression that mentally he is below the average. He further admits that since his trouble he is more easily moved to anger than formerly was the case.

There is now loss of control over a large group of muscles, and the history of the case makes it probable that at the beginning of his trouble the area of diminished control was smaller than at present, and possibly was limited to one or two muscles, or perhaps a single muscle. That the serratus magnus was the first, or one of the first, muscles to be affected seems to me very likely. It certainly is smaller than its fellow; it certainly was at first less irritable to both forms of the electric current than its fellow; it was the only muscle that I could definitely say was not in a healthy condition; it certainly is brought into play whenever the arm is raised in the act of hammering, and most certainly the plan adopted by the patient of holding the elbow close to his side in the act of hammering would enable him to do so without scapular movement, and thus save the muscle over which control had been lost. Again, the slightly faulty position of the right scapula points to some weakness of the serratus magnus. The slight tilting backwards of the vertebral border and the slight elevations of the lower angle are both indications that the serratus is weak, and the large size of the rhomboid muscles on the right side looks as if they had been employed to compensate for the weakness of the serratus and had been used for steadying the scapula. The prominence of the rhomboid muscles, even when the scapula is at rest, coupled with the fact that the vertebral border of the right scapula is ½ in. farther from the middle line than its fellow, led me to think that possibly a bursa or abscess had formed beneath the muscles, and at my request Mr. Godlee very kindly inserted an aspirator at the spot where the prominence is most marked, but with no result.

This case is of interest because of its rarity. It is the first of its kind that I have seen, and for me its chief interest lies in the fact that in many points it offers a striking contrast to all the other cases of professional ailments (and they are not few) which I have seen. In every case of professional trouble that I have seen I have been able, as in this one, to detect peripheral evidence of mischief, but this one is exceptional in the fact that the *peripheral* evidence is evidence of *cerebral* mischief, and enables us to conclude that the lesion is in the brain. This is the only case of hammerman's cramp that has come under my notice, and the only record of similar cases which I can find is in the short paper by Dr. Frank Smith previously alluded to. He was physician to the Sheffield Infirmary, and had seen, naturally, a very large number of hammermen among the patients of the infirmary, and he has placed upon record eight cases analogous to the one we are discussing, and which he called cases of "hephestic hemiplegia or hammer palsy," the word "hephestic," it is perhaps necessary to state, being derived from the Greek word Ἥφαιστος, Vulcan. Of these eight cases six were distinctly hemiplegic in character, while two were cases of brachial monoplegia. In one there was spasm with wasting of the forearm. In one other case there was spasm. In the other cases the symptoms were paralytic, and in four of the cases there was derangement of tactile sense. The ages of Dr. Frank Smith's patients were thirty-one, forty, thirty-two, eighteen, twenty-four, thirty-five, twenty-nine, and fifty-five. He alludes to the points of similarity between these cases and those of writer's cramp, but says that the disease positively differs from writer's cramp in the fact that the cerebral centres are implicated.

It is the difference from rather than the similarity to cases of writer's cramp which constitutes the interest of the case. Cerebral symptoms in writer's cramp and allied professional ailments are infinitely rare, and when present are

very vague and consist at most of some slight dizziness during attempts to exercise the deranged function. In the case we are considering and in Dr. Frank Smith's case cerebral symptoms have been prominent, and, once established, persistent, and in no sense intermittent. Why should this be?

I would offer the following explanation:—Muscular acts differ enormously in the amount of cerebral effort they demand. In some muscular acts we are unconscious of any cerebral effort. This is notably the case in walking, which appears to be almost a purely reflex act, and is often accomplished unconsciously. The woman who walks about gossiping and knitting will do an extraordinary amount of work without apparently giving a thought to her knitting-needles. Even writing—i.e., quill-driving and copying—may be done almost automatically, and so, indeed, may any act in which the tactile sense is largely employed to guide the limb in its movement. An incident which once occurred to myself will serve to show how very automatic a delicate act may become. Some years ago I got a small flake of iron rust into my eye while railway travelling. This caused slight annoyance at the time, but in a day or so I began to suffer from catarrh of the eye, which was excessively painful at times, causing a spasmodic flood of tears and the forcible closing of both eyes. It was in the days when I used a razor, and one morning I was shaving my chin before a looking-glass when suddenly the eyes filled with tears and I closed them; but, nevertheless, I unconsciously finished my shaving, and shaved my chin quite smooth with my eyes shut. There must have been very little cerebration in this act; in fact, had I appreciated what I was doing, I should inevitably have cut myself. My shaving on this morning must have been almost a pure reflex, brought about by constant daily repetition of the same act.

Other acts, again, can never become automatic, and this is notably the case when the movement of the limb is not guided by tactile sense in the performance of the special act. When, for example, did anyone ever thread a needle automatically or unconsciously? During such an act as this there is evidence of strong cerebral effort, as is shown in the face of the sempstress. The taking aim—whether it be at a needle's eye, a bull's eye, or the bit of iron to be forged into a nail—involves the bending of the mind towards the object aimed at; and the aiming at an object against time, as occurs to the pieceworker forging nails, is an act, one would think, which is calculated to cause brain-fag rather than muscle-fag. And the limited number of clinical facts at our disposal seem to point to the correctness of this assumption. When the work done by the muscle is great, and the cerebral effort involved is small, we may well expect the muscle, rather than the brain, to show signs of failure. When, however, the cerebral effort is out of proportion to the mechanical work, as in the repeated act of aiming with a hammer, it is not surprising that, if breakdown occurs, it should occur in the brain. It might be urged that this is not a "professional" trouble—that it is merely a hemiplegic attack followed by post-hemiplegic spasm occurring accidentally in a nail forger. Against this supposition we have to put the fact that his first sign of trouble was in connexion with the professional act; that the spasm of the arm is only seen at its maximum when he attempts to perform the professional act; and that the case does not stand alone, two of Dr. Frank Smith's cases having been very similar in character.

In the average case of writer's cramp I have always contended that, although peripheral evidence of mischief is always present, the evidence does not enable us to say that the lesion is central, although, of course, I very well know that brain cell, nerve fibre, and muscle are practically one. Ordinarily professional ailments never spread to other functions, and certainly the man with writer's cramp is not more likely to become hemiplegic than anyone else. In the case we are considering the trouble, from being merely professional to begin with, quickly spread. This in itself is evidence that in one case the lesion is peripheral and in the other case central, for at the centre where the nerve fibres converge almost to a point any *sudden* lesion is not likely to be limited to the cells connected with one small function only. The nervous system may be compared to a railway with branch lines and a "central" terminus. Now, a fire at Holyhead would not cause any disturbance at Carlisle, notwithstanding that they are both stations on one system of railway, but a fire at Euston would certainly derange the functions of both these outlying stations, and of many others.

The lesion in our case probably began in the part of the centre corresponding to the serratus magnus muscle (for as each limb has its controlling "centre" in the train, so, we must assume, has each muscle of each limb), and thence quickly spread until the right upper limb, the right side of the face, the right half of the tongue and the right leg (?) became involved.

Seeing that the leg is very slightly and doubtfully involved, the lesion, whatever it may be, is apparently almost limited to the left ascending frontal convolution, to an area to which the blood is brought by the ascending frontal branch of the Sylvian artery. Seeing that the onset of the trouble was comparatively sudden, it is not probable that the change which has taken place in the brain is of the nature of a slow degeneration or sclerosis. It is to the vessels of the part to which we must look for an explanation, to hæmorrhage in the area of the ascending frontal artery or embolism or thrombosis of it. There are manifest difficulties in accepting the theory of hæmorrhage or embolism, and against the latter supposition is the absence of any source of emboli. On the whole, I adhere to the belief that the physical basis of our patient's trouble will be found in thrombosis of the ascending frontal branch of the Sylvian artery. In favour of this theory is the fact that his trouble at its commencement was always worse on Monday morning, when the overworked area of his brain had had a period of rest, and when the circulation through it had been, presumably, slow. If we imagine a clot forming in one of the smallest branches and gradually spreading backwards, so as to involve the larger branches of the ascending frontal branch of the Sylvian branch of the middle cerebral artery, we have conditions which, automatically and pathologically, would account for the clinical facts. Thrombosis on the side of the veins leading from this area might conceivably lead to a similar condition, and cause such derangement of nutrition as to prevent the proper control of movement and lead to such a state of things as we are confronted with.

The prognosis in this case is, I fear, not good. Between September, 1885, and February, 1886, his progress has been *nil*, in spite of complete rest, good nourishment, and the therapeutic skill in at least three of our metropolitan hospitals. The deficient irritability of the serratus magnus has disappeared, but even this has not caused more benefit than a similar recovery of normal irritability causes in ordinary hemiplegia. With the exception of this diminished irritability, there have been no indications for treatment in the affected limb. No tender nerves have seemed to demand a blister (which is often of very great use in cases of professional trouble), and no massage or shampooing of the limb would be likely to influence the brain. Rest, if anything, should lead to recovery or improvement; but six months' rest has done nothing, and I very much fear that his trouble is likely to be permanent, and that his loss of control over the affected group of muscles will continue.

Address

ON

MICROBES AND DISEASE,

INTRODUCTORY TO THE DEMONSTRATIONS IN BACTERIOLOGY,

Delivered before the British Medical Association at Brighton, August, 1886,

BY EDGAR M. CROOKSHANK, M.B.

GENTLEMEN,—Many, perhaps, may have expected that the formation of this bacteriological laboratory would be made the occasion for reading papers or holding discussions in connexion with bacterial pathology; it might have been regarded as an opportunity for publishing the discovery of some interesting micro-organism, or for giving an account of recent researches in connexion with the etiology of some morbid process which has been hitherto veiled in obscurity. This, however, is not the case, and for this reason. As is only too well known, we have in England no laboratory devoted to this particular line of research; we have, so far

as I am aware, in London, no institution to which a medical man can be directed where he would obtain a course of instruction or a series of systematic demonstrations. With perhaps one exception, there is no hospital or medical school in London that can be said to give substantial encouragement to this branch of study. Obviously, then, an occasion like the present affords an opportunity of forming a temporary laboratory which may in some measure supply this want, by enabling the busy practitioner, and many others who have not time to visit the laboratories abroad, some opportunity of gaining a practical acquaintance with the subject. Instead of papers and discussions on points of doubt in the past or of hopes of what may be done in the future, we are met to have demonstrations of what has already been done, and more particularly illustrations of those points which, being based upon absolute proof, will undoubtedly bear the test of time and experience. To afford an opportunity of explaining the methods employed in bacteriology, of showing cultivations of micro-organisms, and of demonstrating the microscopical appearances of the pathogenic species, is the purpose for which this laboratory has been arranged. That you should be able to understand the meaning of these mysterious tubes and to appreciate the value of the preparations under the microscope, I will endeavour to briefly describe a few points which indicate the lines of research.

It must be remembered that we have to deal with organisms wonderfully minute, and that we have to study the life-history of each individual species. When we realise the ubiquitous character of microbes, their presence in the air we breathe, the water we drink, and in the earth on which we move and have our being, the difficulties of isolating one particular form from another would seem to be insuperable; nevertheless, with delicate methods and with minute precautions we are able to effect this. The medical man being interested more especially in those micro-organisms which are related to disease, it will be sufficient to give illustrations of the methods which are employed in investigating the life-history of the pathogenic microbes. It must not be supposed that it can be, or ever is, considered sufficient simply to discover by the aid of the microscope a micro-organism connected with a disease in order to proclaim it as the actual cause of the disease. Even if we can, in addition, cultivate it apart from the diseased body, the mere fact of its being able to increase and multiply, and to exhibit peculiar macroscopical characteristics, affords us no evidence whatever of its being pathogenic. From such evidence as this conclusions would be only conjectural, instead of being based upon absolute proof. One cannot, therefore, too often repeat the necessary requirements for accepting the belief in a micro-organism as the *causa causans* of a disease. To Koch we are indebted for laying down concisely what the requirements are. In the first place, the micro-organisms must be constantly found in the blood, lymph, or tissues of the diseased man or animal. To ascertain their presence we must apply our knowledge of practical histology, augmented by many special staining reactions, and in some cases micro-chemical tests. In the second place, we must isolate the micro-organisms from the blood, lymph, or tissues, and cultivate them apart from the diseased body in suitable media, and we must carry on these pure cultivations through successive generations. To isolate and cultivate microbes requires special apparatus—in some cases simple, in others complicated and expensive. It is at this stage of the inquiry that the investigator requires aid from his medical school or from the pathological department of his hospital, otherwise the expense of the apparatus will probably be such a burden to his finances as to prohibit his prosecuting his researches. The suitable medium must be a pabulum which has been rendered free from all pre-existing micro-organisms. This is effected by sterilisation by means of hot air or steam in such apparatus as you have exhibited before you.

We will suppose that we are anxious to investigate some material, such as blood or pus, in which we suspect the presence of a micro-organism. We take a glass rod furnished at one extremity with a platinum wire; we deprive it of any micro-organisms which may have alighted upon it by heating it in the Bunsen burner, and then, as platinum rapidly cools again, we can almost immediately dip the point of the wire into the material to be examined. This test-tube, which is, as you see, plugged with cotton-wool, is filled about one-third with a nutrient jelly. Holding the tube mouth downwards, and twisting out the plug, the inoculating needle is steadily thrust into the jelly and withdrawn, and the plug replaced. These tubes with their contained medium—nutrient gelatine, nutrient agar-agar, blood-serum, hydrocele fluid, as the case may be—are also perfectly germ free; the tubes themselves have been cleansed and sterilised by a temperature of 150° C. for an hour or longer, the cotton-wool sterilised by similar means, and the nutrient medium itself sterilised by exposure to prolonged heat or by boiling on several successive days. If it were not so, the nutrient jellies would in a very short time fall a prey to bacteria of putrefaction, or, in simple language, "go bad." It is sufficient to introduce an invisible quantity of micro-organisms. Nothing will be observable immediately after the inoculation, but in the course of a day or two according to the rapidity of the growth of the particular micro-organism, the temperature of the room, and the nature of the nutrient medium, the germs will increase and multiply in the needle track, and produce some visible change. The resulting appearances are very varied. You have many examples before you: in some there is the appearance of a white thread or a delicate cloud; or the medium has liquefied or become milky, or tinged a pea-green or smoky brown; or a growth or deposit has resulted, of a blood-red, vermilion, purple, or yellow colour.

The method just described is simple and effectual when we have to deal with the presence of one micro-organism, but it may be well asked, What is the course of procedure if there are different species of micro-organisms present together? How can a mixture of micro-organisms be treated so as to isolate them one from another and to test the properties of each? How can they be separated so as to ascertain which are pathogenic and which are harmless? In such a case there is a method which is as simple as it is beautiful. Instead of inoculating our medium in the solid state, it must be first liquefied, and when the mixture of microbes has been introduced the inoculating needle is stirred round and round, and the test-tube tipped and rolled between the fingers. The microbes introduced become disseminated throughout the liquid medium, and if the gelatine is poured out upon a small pane of glass the individual microbes are fixed by the setting of the gelatine, each in a particular spot. In order to effectually separate the different species of micrococci, bacteria, or bacilli, which may be present, from each other, we must employ a method of dilution. A fresh tube of liquefied jelly is inoculated with a droplet from the first tube, and a third tube from the second, and a fourth from the third. Then in the "plate cultivations" which we prepare with these diluted inoculations we shall find that the micro-organisms have been completely separated from each other; the colonies resulting from each microbe giving rise to its own species will be so completely isolated as to leave no chance of their commingling. From these colonies we inoculate fresh tubes of nutrient media, so that at last we have growing in separate tubes all or nearly all the microbes present in the original mixture. The appearance of these colonies before inoculation should be carefully studied, for in some cases they are absolutely characteristic, and in others help to distinguish micro-organisms which resemble each other in form. As an example of a very beautiful and characteristic colony growth, I would draw your attention to the impression-preparations of colonies of anthrax, and several other micro-organisms exhibited under the microscopes. The same method has been also extensively used for studying the various microbes in water; but we must remember that nutrient gelatine is not a suitable pabulum for each and every microbe, and we must therefore supplement our test by means of cultivations in other media. As an example of another medium I would point to the growths on sterilised potato. The outside of the potato is covered with microbes found in the earth, and these must be removed by thoroughly cleansing them and soaking them in a solution of corrosive sublimate. When cut in half with a sterilised knife, the cut surfaces present a germ-free soil, which is particularly suitable for the rapid growth of many, particularly the chromogenic species. The inoculations traced over the potato with no immediate visible effect, will in the course of a day or two develop such a growth—for example, of the *bacillus violaceus* or *micrococcus prodigiosus*—that one might imagine that some violet or red ink had been spilt over the surface of the potato. These pigment-producing microbes are of the greatest interest, for not only is there a wide field for research in the investigation of the chemistry of these pigments, but the very fact that these simple organisms

are endowed with the power of producing such striking colours—are, indeed, miniature laboratories of these beautiful pigments—helps us to understand that other species are equally capable of manufacturing the most virulent poison or of inducing some chemical change, some fermentation, in the blood or tissues which produces a fatal result.

By such means having obtained a pure cultivation, we must carry it on through successive generations. The importance of the successive cultivation cannot be overestimated, for the process does away with the possibility of the fatal result being due to some chemical poison transferred from the material examined to the nutrient jelly. If after carrying on a cultivation through a hundred or a thousand tubes the growth is as virulent as in the first tube, it surely cannot be held that the result is still due to any chemical poison mechanically carried over in the first inoculation, for the original fraction of a drop must have become diluted to such an extent as to be absolutely inert. We must be able with a pure cultivation to produce the disease in question; and, lastly, we must be able to find the micro-organism again in the blood, lymph, or tissues of the inoculated animal. It may be asked, Are there any micro-organisms which undoubtedly comply with all these requirements? The answer is, Most assuredly there are. We may, indeed, very roughly divide the so-called pathogenic microbes into three great classes: first, those which absolutely answer these tests in every particular, and which are therefore undoubtedly the cause of disease; secondly, those in which the chain of evidence is not absolutely complete, but which we nevertheless believe to be the cause of the disease; and, lastly, those which are very probably only accidentally associated with disease. Of the first class, the bacillus of anthrax, the bacillus of mouse septicæmia, or the micrococcus tetragonus may be given as examples. In all these cases we can easily isolate the microbe, we can carry on any number of successive pure cultivations, and we can always reproduce the disease and find the same micro-organism again. Of the second class, we may give as examples the bacillus of tubercle and of leprosy. In the case of the first named the evidence is very strong; but the chain is not absolutely complete, in that, in some cases of tuberculosis, in tissue sections it is very difficult to demonstrate the existence of the bacillus at all, and therefore, until such cases are explained, or until it is more generally accepted that there are forms of tuberculosis etiologically different, of which bacillary tuberculosis is one, there may continue to be doubt in the minds of many as to whether the discovery of this bacillus is of any importance at all. So, too, with the bacillus of leprosy the chain is incomplete, for the bacillus has not been cultivated apart and the disease reproduced by inoculation, and yet, from the veritable invasion of the affected tissues by the bacilli, there can be but little doubt that the bacilli are the active agents in producing the disease. Lastly, we have the class which includes many micrococci, bacteria, and bacilli, present, for example, in the mucous membranes of the respiratory and alimentary tracts, or in the skin, which have been described as characteristic of certain diseases, but about which we must have far more certain evidence before we can maintain that they are more than accidental associates.

DROGHEDA UNION: THE LABOURERS ACT.—Drs. Delahoyde, Callan, and O'Keeffe, medical officers of this Union, having been refused a fair remuneration for inspecting labourers' cottages, &c., under the Act, have served writs on the guardians. The medical officers asked the moderate sum of 5*s.* for each inspection, and they were offered 2*s.* 6*d.* The guardians will defend the action, but there is little doubt that they will be defeated with heavy costs.

SALFORD ROYAL HOSPITAL.—A new wing has just been added to this institution, at a cost of £20,000, which has been paid out of a bequest under the will of the late Mr. John Pendlebury, no appeal having so far been made to the public. Amongst other features, the new wing has three wards, totally isolated from the remainder of the building, for the reception of any cases of infectious disease which may be developed in the hospital, and an operating theatre. The out-patients' department, with the accident ward, is placed at the rear of the building. The hospital, which hitherto has only contained sixty beds, will now be provided with 120. It is expected that the wing will be completed for the reception of patients during the course of next month.

CLINICAL REMARKS
ON
THE TREATMENT OF SYPHILIS BY SUBCUTANEOUS INJECTIONS OF MERCURY.

BY J. ASTLEY BLOXAM, F.R.C.S. ENG.,
SURGEON AND LECTURER ON OPERATIVE SURGERY, CHARING-CROSS HOSPITAL.

THE lecturer mentioned the excellent results which he had obtained at the Lock Hospital and elsewhere in the treatment of syphilis by intra-muscular injections of a solution of the perchloride of mercury. The solution for injection contains six grains of the perchloride to the ounce of distilled water, and should be made fresh for each *séance*. Since he had adopted this method, now a period of some eighteen months, upwards of 1500 cases had been treated with the best results. The sore generally begins to heal very promptly after one or two injections, the secondary symptoms are markedly modified, and after a course of treatment extending over a year, more or less, the patient is enabled to discontinue his attendance. Towards the latter end of the course of treatment the injections may be given less frequently, and as a general rule not more than from eight to twelve grains of the perchloride are injected in all. It is undesirable to repeat the injections oftener than once a week, as otherwise salivation might be induced, and the quantity injected each time (one-third of a grain) is found to be quite sufficient until the next time. There are several advantages attending this method of exhibiting mercury. In the first instance it is only necessary to see the patient once a week, when sufficient mercury is injected to last until the following week; secondly, salivation is not produced, as when the patient continued to take mercury for a whole week away from the supervision of his medical attendant; thirdly, the gastric derangements which are so apt to follow the administration of mercury by the mouth are by this means avoided; lastly, the ease and certainty of the administration, which enable the surgeon to do his own dispensing with a minimum of trouble. A little quinine is generally given during the course as a tonic, but no other form of mercury is administered.

The injection itself is a very simple operation, but certain rules have nevertheless to be observed in order to obviate any inconveniences which might otherwise result. An ordinary glass hypodermic syringe is used with a fine needle (the needle is apt to become very brittle from the action of the mercury on the steel and requires to be replaced from time to time), containing twenty drops of the solution, equivalent to one-third of a grain of the perchloride. After filling the syringe the needle is freed from adhering solutions by washing in order to avoid irritation in its track, and is then plunged deliberately into the muscular tissue of the buttock, selecting for this purpose the spot corresponding to the muscular mass of the glutei into the substance of which the injection is made. If this precaution be observed, no discomfort or abscess formation follows, the only solitary case in which this has occurred being attributable to the injection having been made into the areolar tissue over the trochanter. The pain of the injection is but slight, and soon passes off. It is desirable that the patient should not take active exercise immediately after the injection, as it has been noticed that blood may be effused at the point of injection, giving rise to the sensation of a severe bruise of the part, which lasts for several days. The same effect has followed the puncture of a large vessel, but in any case the result is only transient, and disappears after the lapse of a few days. If for any reason the buttock be objected to as the site of the operation, the injection may be made into the trapezius muscle at a point two inches above the superior angle of the scapula, but the injection into the buttock is attended with less inconvenience.

Mr. Bloxam mentioned that his own opinions were strongly in favour of syphilis being bacillar in origin, thus accounting for the specific action of mercury in the treatment of the disease. In support of this view he alluded to the remarkable researches of Messrs. Eve and Lingard, whom he had furnished with blood and chancrous tissue from patients at the Lock Hospital, the subjects of syphilis.

They have succeeded in detecting and cultivating a bacillus which could generally be found in the blood and tissues of syphilitic patients who had not been subjected to the influence of mercury, or who at any rate had not taken it long. In a contribution to THE LANCET of April 10th, 1886, they say: "In none of the cases from which cultivations were obtained had mercury been administered for any length of time, and a long series of failures have led us to reject entirely cases which have been long under mercurial treatment." With this fact in view, the importance of obtaining a thorough and certain permeation of mercury in the system is apparent, and without claiming any originality in this method of treatment, the lecturer wished to bring before them the extremely favourable results he had obtained from it.

BILOCULAR EMPYEMA; THORACENTESIS; DIVISION OF SEPTUM; COMPLETE RECOVERY.

BY GEORGE PADLEY, L.R.C.P. LOND, &c.,
CONSULTING PHYSICIAN TO THE SWANSEA HOSPITAL.

ON the morning of December 18th last I was sent for to see a young lady, aged between seventeen and eighteen, who had been seized somewhat suddenly soon after midnight with a very severe pain in the right side, preceded by a sharp rigor. She had gone to bed feeling quite well, and awoke at the time named with the above symptoms, accompanied by intense headache and thirst. The only cause to which they could be traced was exposure the previous day to an open window in a covered waggonette. When I saw her she was in a state of high fever, side acutely painful, temperature 104·8° F., pungent heat of skin, pulse 120, respiration 38, subsequently reaching as high as 45; short cough and dyspnœa. These symptoms were soon followed by fine crepitation at the base of the right lung—rusty expectoration, and some friction sound,—in fact, the ordinary symptoms of an attack of acute pleuro-pneumonia. She passed through the earlier stages of the malady favourably, the more urgent symptoms having gradually subsided until the morning of the sixteenth day (Jan. 3rd), when the temperature had fallen to 99·8°. It is needless therefore to give further details of the case, which pursued the ordinary course of this disease, or of its treatment, up to this time. In the evening of Jan. 3rd there occurred a fresh accession of acute symptoms, without any apparent cause beyond some stomachic disturbance, and the temperature rose to 103° and continued averaging from about 101° morning to 103° (on two occasions 104°) evening, until the 24th, when the morning temperature fell to 100·2°. As time advanced the percussion dulness had become more dead, the breath sounds, clear and even exaggerated immediately beneath the clavicle, were inaudible elsewhere, excepting in a space beneath the angle of the scapula; vocal fremitus absent, respiratory movements almost *nil*, voice bronchophonic and distant. Such symptoms, together with the history of the case, plainly indicated effusion within the right chest. The dictum of Dr. Wilks—that "if the case be one of pleuro-pneumonia, and there result, after the acute attack, the same local physical signs (localised dulness with absence of breath-sound, and perhaps distant tubular breathing), then also an empyema is present,"[1] a most valuable inference derived from his large experience—also pointed to the same conclusion. On the other hand, not only was there an absence of any enlargement of the right side, or bulging of the intercostal spaces, but the reverse, the right side appearing rather smaller than the left, and even somewhat contracted. In addition to which there was the localised respiratory murmur near the angle of the scapula, at which spot the air appeared to enter more freely than before. These conditions, though subsequently explained, inculcated caution at this time with regard to operative interference. I could not help also feeling some anxiety as to the state of the lung. The evidences of effusion, however, became more pronounced as the case progressed, and these were corroborated by some displacement of the heart towards the left side, and slight bulging of the right. The general condition had, notwithstanding, somewhat improved, and the average of temperature had fallen about a degree. Before proceeding further, it was thought advisable to have a consultation, and on Jan. 18th Sir Andrew Clark was written to, and kindly came down the following day. He confirmed my diagnosis as to the effusion, but advised postponement of paracentesis for a time, unless rise of temperature, growing embarrassment of the breathing and heart's action, failing general condition, or indications of hectic, should render it necessary at an earlier period.

On the morning of the 24th the patient continued in much the same condition; in the evening, however, there was a marked change for the worse. She had had a restless, feverish day; and when I visited her at about 9 P.M. I found her symptoms had assumed a serious aspect. The axillary temperature was 103°; pulse small, about 135 (partly no doubt accelerated by emotion); breathing distressed; respiration above 40. I therefore determined to postpone the operation no longer, and that night, with the assistance of Mr. Farrant Fry, tapped the chest, under ether spray, with the aspirator in the seventh intercostal space, below where the breath-sounds were heard, and in the posterior axillary line, and withdrew rather more than half a pint of purulent fluid. After this quantity had been taken the aspirator, although the cannula was cleared, ceased to act. As we found the tube of the instrument blocked by fibrinous coagula, we assumed, incorrectly as the sequel showed, these to be the cause of the stoppage. Very material relief, however, especially to the breathing, was afforded by the operation. After the subsidence of some coughing the patient had a good night, having slept calmly for more than four hours continuously. At 11 A.M. (25th) the temperature was 99°, at 9.30 P.M. 100·5°, the pulse and breathing quieter, and the general condition much improved. As, however, the nature and the quantity of the fluid withdrawn, together with some remaining symptoms, indicated the necessity for further relief, a free incision into the pleural cavity was determined on, which was accordingly made the next morning at the site of the previous aspiration, but without the slightest appearance of pus or any other fluid. I had cut into an empty sac. It was evident, however, that there was more fluid pent up somewhere. I passed my finger freely into the cavity, and found the sac from which the pus had been withdrawn surrounded, especially above, by firm adhesions. I then passed a silver catheter through the wound, and made its point project into the ninth interspace, and (as I originally purposed for more efficient drainage) cut down upon it, but with no result whatever in the way of discharge. The remaining pus was clearly encysted above, the dense adhesions felt in that direction probably forming the floor of the cavity. I asked Mr. Fry (who most efficiently administered the anæsthetic, and whose kind co-operation I have to acknowledge) to pass his finger in, and he thought he felt slight fluctuation. I then passed a small long cannula (belonging to the aspirator case) up to this septum—a distance, as near as I could guess, of between two and three inches,—keeping it as near as I could to the parietes of the chest, to avoid the chance of wounding the lung, and through this thrust a trocar, and pushed both onwards. On withdrawing the latter, to our infinite relief, a drop of pus made its appearance at the mouth of the cannula. I at once enlarged the opening thus made with a bistoury, and a gush of pus took place and flowed freely through both external wounds. A full pint was measured, and at least half a pint or more in addition must have escaped. The patient was greatly relieved. A large-sized drainage-tube was inserted through the upper wound into the upper cavity, the lower wound being also kept open to allow of the escape of any pus that might find its way to the lower part of the pleural cavity from the upper cyst. The wounds and drainage tube were then completely covered over with a thick layer of carbolised tow, and this again by some layers of carbolised gauze. A hypodermic injection of morphia was then given, and the patient left to rest.

The morning and evening temperature on the 27th was 99°, and varied but little from this for about a week, when the average was somewhat higher. The drainage appeared perfect, some fibrinous shreds being discharged with the pus, which was not in the least offensive. The secreting action of the cavity first opened appeared also to have ceased. During the subsequent dressings night and morning the atmosphere surrounding the patient was impregnated by the vapour of pine wood oil diffused by

[1] Brit. Med. Journal, vol. i., 1879.

means of a steam kettle, into the water of which three teaspoonfuls of the oil were poured. This, acting as an antiseptic, together with the carbolised dressings, &c., though not perhaps strictly Listerian, contributed, I believe, to preserve the purulent discharge in the pure and inoffensive condition which was maintained during the whole period of the treatment. It is, perhaps, unnecessary to say that all the drainage-tubes and other instruments were immersed in a carbolic lotion before being used.

As the case progressed there were occasional periods of febrile disturbance which had to be met, but as the interest of the case centres in what I have above described, I will not prolong this paper by any detail concerning these, nor occupy space and time by a record of the general treatment, medicinal, dietetic, &c., which was adopted. One thing, however, I may note as having had a favourable influence in hastening the satisfactory result. The pyogenetic cavity being situated at a high level—i.e., opposite the submammary region—I adopted the plan of raising the patient to an upright sitting position during the dressings, and afterwards for half an hour out of bed before them, when she was also desired to walk about the room. The consequence was a freer discharge and more complete emptying of the cavity. This appeared to have a decided effect upon the temperature (which had varied from 99° to 100° or 101°) and upon the subsequent progress of the case. I gradually reduced the length and calibre of the drainage-tubes, until the last used, and finally withdrawn about March 18th, was a portion of a No. 4 catheter à boule, a little fibro-serous discharge being all that remained at that time. The temperature was normal on March 15th and continued so. The upper wound healed satisfactorily soon after the withdrawal of the catheter, the lower one having been allowed to close some time before. The general health rapidly improved, the breath-sounds became more distinct and extended, the percussion note clearer, the heart also returning to its normal position. At one time there was some contraction of the right side, with slight curvature of the spine, but these gradually diminished, and her strength, breathing power, and capacity for exertion steadily increased. I examined her carefully twice in April and again about a week ago. The spine is straight and almost perfect symmetry has been regained. The percussion note and respiratory murmur are normal in front, or very nearly so—not quite so clear or distinct behind, although fairly restored, excepting at the lowest part of the base of the lung. She is able to take active exercise, rides on horseback, mounts stairs or a hill without embarrassment, and nearly as well as before the attack, from which, indeed, she may now be said to have completely recovered.

The case was of course one of great and continued anxiety. In 1879, Dr. Wilks thus writes: "Amongst the numberless affections of the lungs and their appendages which, during the last two or three years, have presented the most difficult problems of treatment, have been localised pleuritic effusions or empyemata." The views upon this question of treatment, especially in regard to operative measures and subsequent management, have undergone a marked change during the last few years. It was stated by an eminent authority, M. Jaccoud, in 1879,[2] that he "had acquired proof that multilocular pleurisies do not bear thoracentesis satisfactorily;" and that "multilocular acute pleurisy ought not to be treated by thoracentesis; puncture is only authorised in order to relieve in emergency the vital indication resulting from really imminent suffocation,"—a doctrine entirely opposed to the lesson derived from the case I have described, as well as probably from some others, more or less similar in character, of which two have been recorded by Professor Morgan of Manchester,[3] and one by Dr. Darwin,[4] though in the latter the empyema pointed in the thoracic wall, and was there opened. There are few also who would now, I think, be disposed to adopt, "even if the case should run altogether a normal course," the heroic measures recommended in an exhaustive article on this subject, largely read and quoted, in Ziemssen's Cyclopædia, involving the frequent cleansings of the pleural sac with water, followed for several days with a solution of common salt; then, after a few days, replacing this with compound tincture of iodine, in 20 to 50 times its bulk of water, or solutions of permanganate of potash or of carbolic acid, "even if there is no fever and the contents of the pleural sac are not fetid."

With regard to the localisation of the purulent cavity, the only instance I have met with, partially corresponding to the one I have given, is recorded by the late Dr. Fagge, in which fluid was found, post mortem, filling the upper part of the pleural cavity, while crepitant lung tissue still existed in the lower part. He states, also, that the limitation of such effusion by adhesion is seldom so complete as to lead to the formation of two or more collections of fluid entirely cut off from one another. Here the limitation was complete.

I have recently (July 27th) examined the patient, and find the right lung fully expanded and the respiratory and percussion-sounds normal.

Swansea.

CASES OF

URINARY DIFFICULTIES OCCURRING IN BOYS.[1]

BY WILLIAM THOMAS, F.R.C.S.,
HON. SURGEON TO THE BIRMINGHAM AND MIDLAND FREE HOSPITAL FOR SICK CHILDREN.

URINARY troubles in children present many points of interest, though they may not perhaps be of so serious a nature as similar conditions in adults. The following cases appear worthy of record, partly from their comparative rarity, and partly from the treatment adopted. All of them occurred at the Birmingham Children's Hospital, and I am indebted to the various resident officers for most of the notes appended.

Extravasation of Urine.

CASE 1.—George R——, aged four, was brought to the Birmingham Children's Hospital on Oct. 2nd, 1880. His mother gave the following history. The child had always complained of pain in his abdomen. When he was three years old his mother was in the workhouse infirmary, and the boy in the children's ward of the same institution. The nurse told his mother that he could not hold his urine, which was constantly dribbling. Medicine was prescribed, and on leaving the infirmary his mother noticed nothing wrong with him, nor was any peculiarity observed about the penis. He was quite well for some time until Sept. 20th, 1880, when he complained of being unable to micturate. During the whole day he strained very hard, holding on by the bedpost like a woman in labour. He was seen by a doctor in the evening, who ordered medicines and fomentations. On the morning of Oct. 1st the penis began to swell, and the doctor recommended him to be brought to the Children's Hospital. I saw him first on Oct. 2nd. The bladder was distended to the umbilicus; there was much elastic swelling of the penis; the scrotum was large and œdematous; and general œdema extended along both inguinal regions, across the pubes, and backwards in the perineum to the base of the triangular ligament. Free incisions were made into the swollen parts, from which clear but slightly blood-stained fluid escaped. The patient was placed in bed and the parts irrigated with weak carbolic lotion (1 in 100). At first a catheter was placed in the bladder, but as it appeared uncomfortable it was withdrawn after three hours.—Oct. 3rd: Urine drawn off at 7.30. Circumcision performed at 10, relieving the glans from the pressure of the still œdematous prepuce. The bleeding was arrested by forci-pressure. Child much more comfortable; only complains of thirst. Some tenderness over the lower part of the abdomen, none elsewhere.

The notes of this case, which were taken daily, show that catheterism was required to empty the bladder for about seven days, after which the urine was voided spontaneously; that it spurted through one of the incisions near the root of the penis on the right side; that an abscess formed in this situation, and a considerable time was required before urine and pus ceased to be discharged from it; that the boy recovered without any permanent injury to the urethra or penis, and that no stone was found. What was the cause of retention and the seat of obstruction to the flow of urine in this case? As a catheter could readily be passed into the bladder, it seems hardly likely that a calculus in the urethra produced the stoppage. The history suggests that a calculus

[1] The substance of this paper was read at a meeting of the Midland Medical Society last session.

blocked the urethra, caused ulceration, and escaped: and the fact that an abscess and a sinus formed near the root of the penis, through which urine passed readily, points to the position of the ulceration. But as no calculus was discovered, the evidence is not complete. The boy had also a tight phimosis, enough of itself to cause obstruction. The extravasation, as in all the cases I have seen among boys, first distended the penis, then passed to the scrotum and along the inguinal regions; so that the phimosis might have had more to do with it than seemed at first apparent.

CASE 2.—That a phimosis may lead to extravasation is clear to me from a case which came under my care some four or five years ago. The patient was a little boy about three years old. The penis was enormously swollen and translucent. Circumcision was at once performed, and on examination of the removed foreskin an opening was discovered on the inner surface, through which the urine had passed. No incisions were made in the skin of the penis in this case, although the swelling was great, and on removal of the prepuce urine gushed out; but the free exit afforded by circumcision quickly reduced the enlargement, and although the penis for some days was of a dusky red, no sloughing or even suppuration occurred.

CASE 3.—Albert H—— was brought to the Children's Hospital in November, 1877, with enormous swelling of the penis and areolar tissue about the pubes. The house-surgeon requested one of my colleagues, who happened to be in the hospital at the time, to see him. Several free incisions were made into the swelling, from which urinous fluid escaped. I saw him shortly afterwards, and ordered irrigation. The case did well in every respect but one. One of the incisions had been so free that the urethra was opened for about an inch, and a penile fistula resulted which afterwards gave me much trouble. In this case, as in the majority of such cases in children, there was no necessity for deep incisions. Circumcision seems to relieve the swelling and drain off the effused urine much more effectually than incisions into the skin, and the urine is not very irritating to the tissues. The severe cases which occasionally occur, such as are reported by Mr. Cooper Forster in his work on the Surgical Diseases of Children, are exceptional. I believe that irrigation is an important aid to treatment, and exercises a considerable effect in the prevention of inflammation and sloughing, which the old treatment by poulticing seemed rather to encourage.

CASE 4.—*Congenital Malformation of Urethra, causing difficulty in micturition; treated successfully by Supra-pubic Cystotomy.*—Edward J. H——, aged four, was admitted into the Children's Hospital on July 3rd, 1885, under the care of my colleague, Mr. G. Elkington. His mother stated that he had never been a healthy child, and always seemed low and pining. He never from his birth micturated properly, the urine either passing in drops or in a stream not larger than a fine needle; micturition was also very painful, the child screaming and seizing hold of the penis, so that he always dreaded it. His bowels were irregular, and the motions were sometimes white and firm, but often like matter mixed with blood. He had once or twice passed a drop of blood at the end of micturition, but never any gravel. He had not suffered from any zymotic disease. He was seized with two convulsive fits last December, and the doctor thought they were due to the urinary irritation. On examination after admission the above account of his symptoms was fully confirmed. The urine could only be passed in drops or in a very fine stream, and sometimes dribbled away; frequently the boy was unable to pass it until he had been placed in a warm bath. His bladder was considerably distended. The urine was alkaline, and contained about a fifth of a column of pus, but no casts could be found. His prepuce had somewhat the hooded appearance seen in hypospadias; the meatus was in its usual position, and a No. 6 catheter could easily be passed for about an inch down the urethra. Several attempts were made, but no instrument or fine probe could be inserted further; the urethra beyond seemed to communicate with the bladder by some fine channel, but the extent and position of this could not be made out. There was no apparent swelling or enlargement of the urethra beyond the constricted part, when straining during micturition.

As Mr. Elkington was going abroad, he kindly transferred this patient to me. I at once determined to open his bladder above the pubes and explore the urethra from its commencement. My reasons for adopting this course were founded chiefly on the uncertainty as to the situation and extent of the obstruction to the flow of urine. It was easy after the event to see that a different course might have been adopted, possibly with success; but at the time, we had to deal with a contraction of the urethra—how produced, and its extent and nature, whether congenital, mechanical, or inflammatory, were not apparent. The operation was performed on Aug. 4th. An incision about two inches long was made in the median line above the pubes, the recti tendons divided, and the bladder exposed; this was freely opened by a transverse incision. The bladder wall, although distended, was much thickened, and its mucous membrane in a state of chronic catarrh. It contained some four or five ounces of thick, stinking, purulent urine. Passing my finger into the bladder, I found the urethra, and easily directed into it a No. 7 gum-elastic bougie; it passed readily to the obstruction, and on examination its point could be felt at the end of the glans penis and on the right of the meatus. The thin stratum of skin covering it was divided and the bougie passed through, withdrawn, and afterwards repassed into the bladder from the meatus. The complete patency of the urethra was thus established. There was some hæmorrhage from the distended veins covering the bladder, which soon ceased. The upper part of the skin wound above the pubes was brought together by two silver wire sutures, the rest being left open for the free escape of the contents of the bladder. Perhaps it would have been an advantage to have washed out the bladder thoroughly, but this was not done, and probably the escape of fetid matter into the areolar tissue gave rise to the subsequent slow progress of the case.

At first the child progressed favourably; at the end of a week there had been no rise of temperature; and ten days after the operation he began to pass all the urine by the urethra; but when the urine ceased to pass over the pubes, inflammatory action took place about the wound, abscesses formed in the areolar tissue above the pubes and delayed healing, besides reopening the communication with the bladder. The quantity of urine passed by the urethra and by the wound varied much, sometimes scarcely any passing by the fistula, at others a considerable proportion, perhaps one-fourth. The urine became clear, and the power of retention, which did not at first exist, was gradually acquired. Four months after the operation a fistula still remained, and on exploring this a buried suture was removed, after which the fistula gradually closed, and the patient was discharged cured. Careful examination still shows that a kind of septum was present near the termination of the urethra, dividing it into two tubes, and acting as a valve to prevent the discharge of the urine. The case, so far as I am aware, is unique.

CASE 5. *Complete Rupture of the Urethra from a fall on the Perineum, with extensive separation of the divided extremities; treated by suture, without catheterism; perfect and rapid recovery.*—Harry J——, aged eleven, was admitted on Oct. 10th, 1885. The day before he had fallen with his perineum across a rail. The fall caused much pain and inability to micturate. The surgeon who was called in attempted to pass a catheter, but without success, and the boy was sent to the Children's Hospital. The resident officer also tried catheterism, but was unable to reach the bladder. I saw him for the first time in the evening of the day of admission. He was then in great pain from distension of the bladder, which reached to the umbilicus. The scrotum was much swollen and dark-coloured, the perineum black from ecchymosis, and there was also some ecchymosis along the right groin. Chloroform was given and the scrotum freely incised on each side; this did not free much fluid; the tissues were gelatinous-looking, and the slight serous discharge from the cut surfaces had no urinous odour. A catheter was introduced into the urethra, but after passing easily for about three inches it seemed to enter a cavity which was evidently not the bladder, although about a tablespoonful of bloody urinous fluid was withdrawn at each attempt. The perineum was incised, and on passing the finger into the wound the point of the catheter was felt in a large cavity, which was filled by coagulated blood and some urine. It was determined to wait until morning before any further operative proceedings were undertaken. In the meantime the cavity was ordered to be freely syringed out with weak carbolic lotion and the surface of the scrotum and incisions irrigated. The bladder was aspirated above the pubes and 23 oz. of slightly turbid urine withdrawn. Five minims of tincture of opium to be taken every four hours.

Oct. 11th: Has passed a fairly good night. Swelling of scrotum much diminished; no urine passing by incisions. Chloroform administered, the boy placed in the lithotomy position, and the perineum incised in the median line until the bulb of the urethra was exposed and the cavity of the perineum fully opened. The urethra was then seen to be completely torn across just behind the bulb; the posterior part was retracted and separated for about two inches, lying deeply in the perineal cavity. A catheter was easily passed through this into the bladder, and some urine withdrawn. A lithotomy staff was next passed along the whole extent of the urethra into the bladder, and the separated parts brought together and stitched with three silver wire sutures. The sutures were passed completely through the wall of the urethra and each tied outside in a reef knot, the ends being cut short. With the staff still in the bladder, the membranous part of the urethra was opened by an incision such as is made in lithotomy to allow of the escape of the urine by the perineum, and, by keeping the stitched urethra free from contact with that fluid, to give a better chance of union. A tube was passed through the incision into the bladder, the boy placed in bed, and irrigation continued.—12th: Patient looks comfortable; has passed a good night; temperature normal. A black clot fills each incision in the scrotum; urine passes freely by the tube. A warm water enema was administered, by which the bowels were freely moved.—13th: Continues improving; tube had partly slipped out and was completely withdrawn, as the urine escapes freely without it.—16th: As there appeared to be rather an ammoniacal odour about the wound, a flexible indiarubber catheter was passed into the bladder from the perineum. The urine withdrawn was clear, pale straw colour, and free from any ammoniacal odour. The same catheter, a No. 7, was passed down the urethra into the bladder quite easily. This was the only time an instrument was passed along the urethra from the time of the operation. For the next few days the boy steadily improved, and on the 20th it was noted that all the urine passed by the urethra, and that the perineal wound was rapidly closing.—Nov. 13th: A careful observation was made of the size of the stream passed during micturition; it was estimated to be as large as a No. 8 catheter, and was attended by no straining or pain.—23rd: Perineal wound quite healed; boy to get up.

I have seen this patient about every month since, and he continues in every respect well. The size of the stream of urine during micturition is larger than when he left the hospital; no induration or pain is experienced at the site of the sutures. It will be observed that these were not removed; they became so quickly buried in the wound, and excited so little irritation, that it was unnecessary to disturb them. Hitherto they have given no trouble, and the boy would not be conscious of their presence if he had not been told.

I believe there are several cases on record in which suture of a ruptured urethra has been practised; but as yet it scarcely seems to be a recognised proceeding, as our surgical text-books say so little about it. My friend, Mr. Hawkins, had a somewhat similar case to the above, with an excellent result; and Mr. Mayo Robson has, I believe, excised a stricture and successfully united the two parts of the urethra. Mr. Birkett's case is also well known. But every additional case is worth recording, as showing that in such injuries to the perineum from falls or sudden impact, attended with retention of urine, we ought at once to dissect down to the urethra, ascertain the amount of damage, and endeavour to repair it. Such a course of proceeding, more frequently followed, would do away with the surgical difficulties in the relief of the miseries of traumatic stricture by preventing its occurrence.

PRESENTATION TO SIR DYCE DUCKWORTH.—On Saturday last the matron, many of the sisters, and nurses of St. Bartholomew's Hospital assembled in John ward to present a testimonial to Sir Dyce Duckworth on the occasion of his resigning the medical lectureship in the nursing school of the hospital. The testimonial consisted of a Doulton ware salad-bowl, mounted in silver, and suitably inscribed, together with a large photographic album and an address. Sir Dyce Duckworth expressed his thanks for the very handsome gift, and regretted that he was compelled to give up teaching in the nursery school, which he had always been much interested in since he began the lectures nine years ago.

NOTES OF A CASE OF GASTROSTOMY.

BY GEORGE A. HAWKINS-AMBLER, L.R.C.P.I., &c.

D. L——, master dyer, aged sixty-one years, came under my observation on November 14th, 1885, when I was called to him in consequence of a severe attack of hæmorrhage, which came on suddenly whilst he was standing at his office desk early in the morning. He "felt something cut or break" in the throat, and blood came up in mouthfuls to the extent of about two pints. Complete rest in bed, the hypodermic injection of three grains of ergotin, and the exhibition of half-drachm doses of oil of turpentine in egg albumen every three hours was followed by entire stoppage of the bleeding. These circumstances—the patient's age, hæmorrhage easily controlled, with the following symptoms—led me to diagnose cancer of the gullet. Family history good; no history of syphilis. With the exception of repeated attacks of quinsy he has always enjoyed good health. For two years past he has felt a slowly increasing difficulty in swallowing, and in July last consulted a surgeon who, by dilating the œsophagus with bougies, enabled him to swallow with more ease for some months. The last time the bougie was passed the instrument was stained with blood, and he grew alarmed and never went again. From July to November he underwent no further treatment, but lived on thick soups with such solids as Yorkshire pudding, which he could swallow with difficulty, and milk foods. A loss of some two stones in weight, however, indicated the progress of the disease and insufficiency of food; but he carried on his business regularly up to Nov. 14th. The recent hæmorrhage precluded the passing of a bougie; but I learnt from his former attendant that the constriction was opposite the manubrium sterni. The hæmorrhage relieved the constriction somewhat, so that for a fortnight later he could swallow dry oatmeal porridge. I asked for the opinion of Dr. T. Kilner Clarke of Huddersfield, which confirmed my diagnosis of cancer, and suggested a gastrostomy as the only thing to be done. I may add there were no physical signs whatever to help the diagnosis. As the patient could not be adequately fed, and the weakness increased rapidly, especially after a second attack of hæmorrhage, the operation was done, as soon as patient gave his consent, Dec. 17th, by Dr. Clarke.

Half a pint of Benger's food was given by the mouth at 6.30 A.M. and a Slinger's nutrient suppository at 7.30. The operation commenced at 9 o'clock A.M. Ether was administered, but was soon changed for chloroform, as the action of the abdominal muscles was tumultuous. The margins of the stomach being ascertained by percussion, an incision four inches long, commencing three-quarters of an inch above the edge of the ribs, was made in the line of the fibres of the rectus abdominis, an inch and a half internal to the left nipple-line viz., half an inch to the inner side of the linea alba. After the integument and fascia had been divided, the fibres of the rectus came into view, and were separated by the handle of the scalpel, and held apart by retractors till the peritoneum was reached. This was divided on a director, and the stomach readily found and recognised by its thick substantial coats and arrangement of vessels, and drawn well forwards. Two silk loops were inserted into the stomach at an interval of one-third of an inch apart at its most presenting part, and four silk sutures on either side, each traversing half an inch of the serous and muscular coats of the stomach, brought its wall into close contact with the margins of the wound, leaving exposed at the bottom of the wound a piece of stomach the size of a sixpence. The peritoneum was united with carbolised catgut sutures, and the margins of the wound carefully approximated above and below the loops in the stomach. A small piece of drainage tubing was placed on the lower part of the wound, and the whole covered in with salicylic silk and bandages. Antiseptic precautions were used throughout. The patient was fed every two hours with Slinger's suppositories, which proved of great value, and injections of peptonised milk and other foods alternately, all of which were retained. The rectum was washed out with warm water prior to each nutrient injection, which gave the patient great ease and comfort, and the bowels were relieved daily. The temperature kept at and below normal for a week after the operation, and there was no bad symptom throughout. The wound was dressed under the spray every second day; the drainage-tube was removed at

the second dressing. On the fifth day the operation was completed by an incision in the stomach wall between the loops, which were then removed. Previous to this the patient was given separately the two parts of the effervescing draught, the effervescence of which in the stomach assisted the operation by dilating that organ and bulging it forwards. A piece of gum elastic catheter (No. 9) was now inserted, some Benger's food syringed through, and the opening kept patent by the insertion of a piece of tent, which was removed in twenty-four hours. At first there was great leakage, the dressings—tenax, tissue, and flannel binders—being saturated at each feeding. But this slowly lessened, and the skin, which was extremely irritated and inflamed by contact with partly-digested foods, healed under the application of vaseline and zinc ointment. The wound filled up, until on Jan. 25th there was merely a round aperture for the insertion of Krohne's apparatus (Bryant). A tent has since been inserted for a few hours to dilate the aperture, which has a tendency to close. Digested foods, soup, beef-tea, eggs, wine, and whisky are administered every three or four hours to the extent of a pint each time, and there is no gastric discomfort. The bowels act daily with the warm water enema. The patient gains strength, sits up twice a day, and is only inconvenienced by the constant expectoration of saliva, mucus, &c. The gain in strength and comfort resulting from the operation is most marked and gratifying, and there can be no question that life has been considerably prolonged by it.

I have ventured to describe the case at this length because (1) the operation has been considered to be on its trial; (2) the books do not describe it as fully as the student and young practitioner desire; (3) because of one or two points in the operation now described which seem worthy of notice—viz., (*a*) mapping out the margins of the stomach before making the primary incision; (*b*) the advantages derived from making the incision parallel to the fibres of the rectus, lessening hæmorrhage, and providing, as has been pointed out, a sphincter for the opening subsequently; (*c*) and finally, in performing the second part of the operation—viz., the opening into the stomach cavity—it is, unless the stomach be distended, extremely easy to fail, from the mucous coat being so easily separable from the serous and muscular coats; this is obviated by the exhibition of the effervescing draught separately as described before proceeding to the completion of the operation.

Kirkburton.

A CASE OF ACTINOMYCOSIS.

By WILLIAM O'NEILL, M.D., M.R.C.P.,
HONORARY PHYSICIAN TO THE LINCOLN LUNATIC HOSPITAL, ETC.

IN November of last year Mr. S——, a farmer, fifty years of age, consulted me about a pustular eruption on the left wrist and forearm and a slight apparently glandular swelling under the right ear, both affections he had noticed in the early part of the preceding month. There were also four or five smaller swellings in the neighbourhood of the clavicles and one in the left axilla. As the patient was somewhat out of health, I thought the tumours might either be of a strumous character or might be owing to a cachectic state of the system from defective sanitation. The patient thought he was suffering from blood-poisoning, and suspected the water he had been drinking, but on investigation the water and drainage were found to be good. He was ordered a mixture containing iodine and arsenic, and as a local application for the eruption citrine ointment. In a few weeks the skin eruption had almost disappeared and the tumours were slowly diminishing in size, when in January of this year he was attacked with inflammation of the tonsils and an aphthous-looking state of the mouth. In February under suitable treatment the mouth was better, but two or three new enlargements had appeared, and some of the old ones had increased in size. The one below the ear was as large as a small hen's egg. It was smooth, nearly painless, elastic to the touch, and slightly movable. Under the chin there was a globular enlargement as big as a filbert, and another of about the same size on the back of the head. The patient was now ordered a mixture containing solution of perchloride of mercury and iodide of potassium, and an ointment of iodide of ammonium. In March the state of things was looking more favourable, when unfortunately severe bronchitis set in, which on its subsidence left matters much worse than before. The tumour in the angle of the neck had extended in all directions, more especially downwards. It had also suppurated, and two or three sinuses gave exit to a whitish purulent fluid, which frequently contained small yellowish particles. The sore generally presented a reddish granulating surface, but occasionally dark-coloured scabs would form on it. Several of the smaller tumours on the lower part of the neck had nearly disappeared, but the one under the chin was still large enough to be uncomfortable, and the tumour on the back of the head had become as big as a walnut, and although unulcerated, was so painful that he could hardly sleep on his back. A small swelling had also formed under the left ear. The irritation of the system produced by so many tumours caused an increase of temperature and a hastening of the pulse—however, not so much increase of temperature and frequency of pulse as might have been expected. At this stage of the disease the patient began to take a combination of iodide and bromide of ammonium, but a few weeks ago, seeing that most of the tumours, especially the one in the angle of the neck, continued to enlarge, and being in some doubt as to their exact nature, I advised him to go up to University College Hospital, with the object of having them removed either then or on some future day. Consequently, on June 4th Mr. Redman, a student friend of mine, showed the patient to Mr. A. E. Barker, who kindly examined him, and came almost to the conclusion that he was suffering from actinomycosis. Since the patient returned from London I have been able to find some of the micro-organisms which are supposed to be peculiar to the disease.

I believe it is the opinion of those who have studied the subject of actinomycosis that the malady is communicated from animals to man. There is a probability that the disease may have been thus conveyed in this instance, for a few weeks before the affection made its appearance in Mr. S—— he had been "dressing" calves affected with a disease which he called "ringworm." I have had a photograph taken of two young animals in which so-called "ringworm" is well marked. In these animals there are no lumps at present under the jaws, or in or about their mouths. Ringworm began in them, as well as in several others, by the hair falling off, a reddening or inflammation of the skin, and the formation of ash-coloured scabs, more or less thick, according to the severity of the disease in the part affected. The disease is caused by a fungus which can be destroyed by sulphur or by a mercurial preparation, notably by corrosive sublimate. Whether the fungus of the ringworm in these animals is the same as the parasite of actinomycosis, I am unable at present to say; but, if not identical, I am inclined to think that both parasites are closely allied.

Taking into consideration the source whence the infection of antinomycosis is derived, it will be seen that the disease must have presented itself from time immemorial, and the reason why it has been unrecognised and overlooked and has not been described as a substantive disease until the last few years, is most probably owing to its being confounded in certain of its stages with scrofulous and cancerous affections—with scrofula in its early stages, and with cancer in its ulcerated stages. That it is a serious complaint there cannot be much doubt, for it appears that one-half of the cases which have been published have died, and this serious result is not to be wondered at when authorities on the affection tell us that the disease may attack almost any organ in the body. The fungoid disease may have contaminated Mr. S—— first in the wrist, from the wrist it may have extended to the axilla, thence to the neck, and even the parasite may have had something to do with the causation of the bronchitis.

As to treatment, iodine, arsenic, and mercury have, I think, some power over the disease in its early stages, for the tumours, late in making their appearance, dispersed whilst the patient was taking these medicines, and even the large lumps, on account of their becoming smaller and more movable on one or two occasions, gave hope of their disappearing. After all, in a case of this kind, where actinomycosis appears in the shape of external tumours, the most expeditious and the best treatment would, I believe, be removal by surgical operation.

Lastly, I would remark that the history of the discovery of actinomycosis is very interesting. According to M. Bricon the parasite was first discovered by Italian veterinary

surgeons, one of whom, Rivolta, wrote about the disease in 1868. In Germany Bollinger rediscovered it in 1877, and gave it the name by which it is at present known. Israel was the first to describe a case of it in a man in 1878, but since then several cases of the disease have been published on the Continent and two or three in this country.

Lincoln.

A CASE OF

SEPARATION OF THE UPPER EPIPHYSIS OF THE LEFT FEMUR.

BY A. W. MAYO ROBSON, F.R.C.S.,

SURGEON TO THE LEEDS GENERAL INFIRMARY, LECTURER ON OPERATIVE SURGERY AT THE YORKSHIRE COLLEGE.

IN the article by Mr. H. Morris in Holmes' System of Surgery occurs the following passage:—"Several supposed examples of this accident have been recorded, but I agree with Mr. Holmes in thinking that they are not conclusive as to the real existence of this lesion" and again in the same page, "fractures of the neck of the femur are hardly known in childhood, and the upper epiphysis is so small and lies so completely within the hip-joint, that its disjunction is unknown except perhaps in the fœtus." The case related below is certainly either a fracture through the neck of the femur or a separation of the upper epiphysis; I believe it to be the latter, and in this opinion I am supported by my colleagues at the Leeds Infirmary, to whom I showed the patient. The notes have been furnished by my dresser, Mr. Roper.

W. C——, aged five, was admitted in March, 1886, into the Leeds General Infirmary on account of lameness due to

shortening of the left lower extremity, with the history of having been thrown up four years previously by her uncle, who failed to catch her, letting her fall heavily on the left side. Beyond rest no treatment had been followed out, and the mother was unaware of any other accident having happened to the child, but she had noticed the limp to become more marked during the last few months.

The accompanying photograph, kindly taken for me by Mr. Barling, clearly shows the position of the deformed left limb as the patient stood. The signs on admission were as follows:—Marked limp on walking, the patient leaning to the left; well-marked eversion of the foot, which could, however, be brought parallel with the right without giving pain; ability to completely flex and extend the thigh. Measurement from the anterior superior spine of the ilium to the malleolus showed three-quarters of an inch of shortening on the left side, and from the same point to the lower border of the patella gave a like result, but the distance from the top of the great trochanter to the malleolus was the same on both sides. Nélaton's line showed the left great trochanter to be raised three-quarters of an inch, and Bryant's line was three-quarters of an inch shorter on the injured side. The folds of the buttocks were well marked. On flexing and rotating inwards the left femur the fingers could clearly feel the neck of the femur as far as the head, but the prominent part of the caput femoris was apparently in the acetabulum, and was not attached to the cervix. The muscles of the limb were well developed, and a thickened sole on the left boot almost abolished the limp.

A Mirror OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

UNIVERSITY COLLEGE HOSPITAL.

IMPACTION OF A FOREIGN BODY IN THE ŒSOPHAGUS; LARYNGOTOMY; TRACHEOTOMY; RECOVERY; REMARKS.

(Under the care of Mr. CHRISTOPHER HEATH.)

THE following is one of a class of cases which not unfrequently present themselves in the casualty department of large hospitals, and in which the necessity for immediate interference is imperative. With a history such as that given, after exploration of the pharynx without the discovery of any foreign body, the indication is clearly the line of treatment adopted in this case, the completion of the diagnosis being left until the subsidence of the urgent symptoms. There are few conditions in which a more prompt action or greater self-reliance is required. For the following notes we are indebted to Mr. Hugh Armstrong, house-surgeon.

On May 22nd, W. S——, a boy aged twelve, was brought to University College Hospital casualty room by the father, with the history that while at dinner the boy had fallen back choking. When seen by the house-surgeon the patient was insensible, motionless, much cyanosed, and making strong inspiratory efforts that appeared to draw a small quantity of air into the lungs. Nothing could be felt at the back of the mouth; and, as the case was extremely urgent, laryngotomy was performed with a penknife, and the opening in the crico-thyroid membrane kept patent with a pair of sinus forceps. There was a little bleeding, chiefly venous, which subsided as soon as the asphyxial condition was relieved. The opening, however, did not seem sufficient, so tracheotomy was done, and a tube tied in, the cricoid cartilage not being divided. The boy quickly recovered consciousness, and in about a quarter of an hour was taken into a private ward, put under chloroform, and examined. Nothing could be felt in the fauces or pharynx with the finger. A No. 6 English catheter was then passed along the forefinger down the pharynx, and, when about two-thirds had disappeared, an obstruction was felt, beyond which the instrument would not pass; for it doubled up when moderate pressure was made. A full-sized instrument with a stylet in it was next tried. The obstruction was again felt, and, after somewhat firmer pressure, the catheter slipped on into the stomach. There was no blood on the end of the instrument when withdrawn. A feather was afterwards passed up the larynx through the tracheotomy opening, but no obstruction felt. The tube was replaced, a canopy arranged over the bed, and steam allowed to play under it. While recovering from chloroform the boy vomited a large piece of meat an inch and a half long, three-fourths of an inch broad, and about half an inch thick; and when quite conscious gave the house-surgeon to understand that the obstruction had disappeared. Milk and beef-tea were ordered. The temperature rose to 102° on the following evening, but never went higher. A piece of wet boracic lint was laid over the mouth of the tube, which was kept in for forty-eight hours. When this was withdrawn the wound was covered with wet lint, and by June 8th had completely closed. The boy's voice had regained its strength within a week later.

The after-treatment consisted in keeping the air of the room warm and moist, but the steam kettle was removed on the second day, when the temperature was 102°. No crepitation could be heard over any part of the chest, and the pulse respiration ratio was unaltered.

Remarks.—The great cause of the asphyxia in this case is

doubtful. From the distance which the catheter was passed it may be assumed that the meat lay at the upper part of the œsophagus. But whether this was the position when the boy was brought to the hospital is questionable. Two views suggest themselves to explain the dyspnœa. Either that the fragment lay partly over the orifice of the larynx partly within the œsophagus, or that all lay behind the larynx and reflexly led to spasm of the glottis. The character of the dyspnœa accords better with the latter view, as it was distinctly stridulous. The boy's symptoms, however, were too urgent to allow time for fetching instruments, or an œsophageal bougie would have at once relieved his condition. Laryngotomy was selected on account of the rapidity with which it could be done, and the laryngeal character of the dyspnœa. But the opening was insufficient, so it was decided to perform tracheotomy. The question arose as to whether the tube should be removed after the meat had been vomited. But, considering the somewhat rough handling with the feather that the larynx had been subjected to, it was thought safer to leave it in. This course was justified next morning, for the boy was unable to breathe when the tube was plugged.

NEWCASTLE-ON-TYNE INFIRMARY.

A CASE OF SARCOMA OF THE INTERNAL POPLITEAL NERVE.

(Under the care of Dr. G. H. HUME.)

FOR the following notes we are indebted to Mr. H. Bramwell.

Joseph J——, aged forty, a miner, was admitted on Jan. 28th, 1886, complaining of a swelling behind the right knee and of shooting pains down the leg. He had noticed, four months since, that while at work he occasionally had shooting pains down the outer side of the leg; these pains had become more frequent, and could always be produced by forcibly bending or fully stretching the leg. There has also been sharp pain across the sole of the foot at the base of the toes. A few weeks ago he noticed a lump behind the knee. His health generally has not been so good as usual during the past year, and he has lost in that time a stone and a half in weight. He is a tall, well-developed, but lean man, with pale face and anxious expression. Towards the lower part of the right popliteal space in the median line is a tumour which extends downwards to the arch of the gastrocnemius. The swelling is under the deep fascia, being freely movable when the leg is flexed; fixed, or at most slightly movable laterally, when the leg is extended. Pressure on the tumour causes the shooting pains. The diagnosis arrived at was that the tumour was probably a sarcoma, and from the direction of the shooting pains it was believed to implicate the short saphenous, or possibly the internal popliteal nerve.

On Feb. 4th the tumour was cut down upon, and found to be a soft oval-shaped growth, extremely vascular, intimately connected with the fibres of the internal popliteal nerve, and having the short saphenous nerve stretched over it, the latter fact being that which had mainly given rise to the symptoms. As the growth had not acquired adhesions to adjacent structures, it was separated from the sheath of the vessels, and the internal popliteal nerve with which it was incorporated was cleared for a distance above and below. The nerve trunk was then divided, so as to remove with the growth a portion of healthy nerve at either end. The length of nerve removed, including the tumour, was three inches and a half. The wound healed slowly but without complication, and the man returned to his work as a miner.

Description of tumour.—The growth was encapsuled in the sheath of the nerve, and appeared defined even at the two ends; but there it could not be separated from the substance of the nerve on account of a portion of the nerve fibres passing through it. The bulk of the substance of the nerve lay behind. A longitudinal section of the growth had a coarsely fibrillated appearance; to the naked eye it consisted of strands of fibres pushed apart by soft, easily broken-down material. It was exceedingly vascular, large veins being visible underneath the capsule, and in the interior were one or two blood cavities filled with clot. The minute examination corresponded with this appearance. Masses of small round-celled growth lay between the implicated nerve fibres, and into this new growth numerous hæmorrhages had taken place. In the centre of the tumour a blood cavity three-eighteenths of an inch in diameter had been formed.

Remarks by Dr. HUME.—The interest of this case is twofold. It is clear that with the further growth of the tumour, and the consequent expansion of the supporting nerve fibres, the tendency of the new cell material to break down under the pressure of the blood would be increased. Probably in no long time the tumour would have been thus converted mainly into a blood-containing cavity. Such hæmorrhages are, of course, produced by the rupture of bloodvessels, and if it chanced that a vessel of some size were opened into, the tumour would have at once become pulsatile and have closely simulated an aneurysm. In its position with reference to the popliteal artery the resemblance to aneurysm would have been very close, and correct diagnosis correspondingly difficult. The case therefore illustrates the manner in which sarcomatous tumours so frequently come to simulate aneurysm. It also illustrates one mode of production by that vague class of pathological formations referred to and described in surgical works under the name of blood cysts. Perhaps the best known of such cases is that related by Mr. Moore in the Medico-Chirurgical Transactions for 1886. In that case the cyst originated in the popliteal nerve, became adherent to surrounding parts and in some portions was composed of "old tough lymph" which contained "small oval cells having indistinct nuclei." Anyone now reading Mr. Moore's narrative will be struck with the probability that the tumour was in reality a sarcoma. The case is further of interest as regards the degree of usefulness of the limb after division of its chief nerve trunk. The leg and foot, so far as cutaneous sensibility and muscular power are supplied by the posterior tibial nerve, were of necessity paralysed. Happily the muscular branches of the internal popliteal to the two heads of the gastrocnemius, being given off, as frequently happens, at quite the upper part of the ham, escaped division, so that some power of extending the foot at the ankle remained. Cutaneous sensibility of the outer aspect of the leg above the ankle and of the foot, which depends on the external saphenous nerve (tibial communicating), also remained, as that nerve had been merely stretched over the tumour and could be pushed aside. The muscles on the front of the leg and the peronei were not, of course, affected. On the whole, the impairment of walking power was wonderfully less than might have been expected, and did not amount to more than a slight limp. The insensibility of the sole of the foot hardly seemed to cause inconvenience; the leg still afforded a firm support, and the patient is now following his employment as a miner.

BRITISH MEDICAL ASSOCIATION.

FIFTY-FOURTH ANNUAL MEETING,

HELD AT BRIGHTON, 1886.

THE third general meeting, held on Thursday, Aug. 12th, of which a brief account was given in our last issue, was marked by some interesting proceedings—namely, the presentation of awards, and the invitation by delegates from the United States to members of the Association to attend the forthcoming International Congress.

Sir B. W. FOSTER, as President of the Council, related the circumstances under which the Council had this year decided to award the special Order of Merit instituted by the Association in 1877. The badge of that Order was a medal in gold, silver, or bronze, and it had only previously been thrice awarded. The first recipient was Dr. Davies of Swansea, who had heroically distinguished himself in saving several lives at a colliery disaster in South Wales. On the second occasion it was given to Surgeon-Major Reynolds, for his conduct at the terrible conflict at Rorke's Drift. The third award was made to Dr. W. Farr, whose life had been spent in the study of vital statistics, and in establishing a system of registration which had been adopted by all civilised communities. They now proposed to reward another kind of merit, which had never been recognised by the Association, and too little recognised by the world at large. There were services rendered to every body of men in their corporate capacity—services which developed

their power, and raised their social and professional status—services too often forgotten, but which left a lasting mark. The Medical Reform Committee was presided over by a gentleman who never lost heart or courage, or failed in industry. In the last Parliament a Bill was introduced which, though imperfect in many of its details, not rising to the level which they wished, yet contained two of the principles for which he had fought so earnestly and well. One of these principles was that every medical man should be thoroughly qualified before he was placed on the Register, and the other was the recognition of their right to be represented on the General Medical Council. For years they had been fighting this battle, and had at last in this Bill got the principle recognised, although not to the full extent which the medical profession had a right to claim.

The PRESIDENT (Dr. Withers Moore) then invested Dr. Waters with the gold medal for distinguished merit of the British Medical Association, and said that he felt very proud to be the instrument of conferring upon him this great honour, which he hoped he would many years enjoy.

Dr. E. WATERS, who was loudly applauded, said he need not say with what feelings he appeared before them. He appreciated the high distinction conferred upon him—a distinction which, of all others, he would have desired to crown his life, and which he trusted he should always prove himself not unworthy of. He had always been, and would always be, a devoted, loyal member of the British Medical Association, from the time when, as a stranger, he had settled in Chester, and had found in the Lancashire and Cheshire Branch life-long friends. He said when, in 1859, he was chosen President of that Branch, he desired and cared comparatively little for the opinion of the general public provided he could only win the esteem and regard of his professional brethren. Subsequently he was elected to the high post of President of the Association, and thenceforth determined to discharge zealously any duty that the Association might impose upon him. He briefly referred to the action of the Medical Reform Committee, and said, in conclusion, that the reward which he had earned at the hands of a body representing 12,000 medical men exceeded his wildest imaginings. He regarded it as one of the greatest treasures that he could have obtained, and he disregarded all else in comparison with what had been conferred upon him.

Sir B. W. FOSTER then announced that the prize founded by the late Dr. A. P. Stewart for the best work done in contagious diseases, had been awarded to Dr. Robert Cory, whose self-sacrificing inquiry into the subject was well known. He also announced that the Middlemore Prize in Ophthalmology had been awarded to Mr. George Berry and Mr. Adams Frost.

The American delegates were then introduced—viz., Drs. Davis (Chicago), Pancoast (Philadelphia), Shoemaker (Philadelphia), Brodie (Detroit), Gordon (Portland), Wylie (New York), Earle (Chicago), Romsey (Michigan), Hitchcock (Kalamagoo), and Peck (Devonport, Iowa).

Dr. N. S. DAVIS commenced by returning thanks for the opportunity afforded them to address the meeting, and for all the courtesies they had received. He related the steps that had been taken to promote the meeting of the ninth International Congress in Washington next year, from Sept. 5th to the 13th, and said that the idea of inviting the Congress to the United States had originated with the late Samuel D. Gross and Austin Flint, sen.—those Nestors in surgery and medicine, who had both gone to their rest. Dr. Flint, at the meeting of the American Medical Association in 1884, had reminded them that theirs was the only organisation representing the whole profession in America, and that steps should be taken to invite the Congress. The invitation was sent, and, after inevitable differences, an organisation had been formed representative of all the profession in every State, as well as the army and navy departments. English, French, and German would be the official languages, and four secretaries had been appointed to each of the seventeen sections. He asked the members of the English profession to come in force, and promised them a welcome as cordial as Americans know how to give. An influential local reception committee had been appointed; and with respect to transit, he begged the members of the British Medical Association to join in exerting their influence to induce the steamship companies to carry members across the Atlantic at reduced rates.

Drs. BRODIE and PANCOAST also briefly addressed the meeting, and repeated the assurances of a hearty and cordial welcome to all who attended the Congress.

A hearty vote of thanks to the delegates was then passed.

Mr. J. R. HUMPHREYS (Shrewsbury) then brought forward a memorial to the Government, proposed by the Shropshire Branch, with reference to the conferment of peerages upon medical men; but the motion, on being put to a division, in a greatly attenuated meeting, was negatived.

The fourth general meeting was held on Friday morning, Aug. 13th, when an address on Public Medicine was delivered by Dr. Mapother of Belfast.

On the conclusion of the address, a vote of thanks to Dr. Mapother was moved by Dr. Taaffe, seconded by Surgeon-General Cornish, and unanimously carried.

Dr. GRANT (Ottawa) expressed the pleasure with which he had listened to the address, and took occasion to return thanks for the hospitality awarded to the American, colonial, and foreign visitors. He trusted that at the International Congress they would see a large number of the members of the British Medical Association. As representative of Canada, he warmly thanked Sir B. W. Foster and those associated with him in the House of Commons for the efforts successfully made in the cause of medical reform.

The concluding general meeting was held in the afternoon of Friday, the 13th inst.

Dr. WATERS moved the adoption of the report of the Medical Reform Committee. He said that in the Medical Act of 1858 the chief points gained were the foundation of a Medical Council, the establishment of reciprocity, and the formation of a Medical Register. In a few years imperfections in the Act became manifest, and the Association took steps to secure its amendment in the way of direct representation of the profession on the Medical Council. The struggle had lasted twenty-five years, and they had now gained large concessions. Dr. Waters said that he did not intend to become a candidate for a seat on the Council, but it would be for the Association to select men who would do them credit and who would be recognised by the Council as able men.

Dr. GRIMSHAW, Registrar-General of Ireland, seconded the motion. He had been a member of the committee until his official duties necessitated his retirement.

The report was then unanimously adopted, as was also the report of the Parliamentary Bills Committee.

Mr. SIBLEY moved the adoption of the report of the Scientific Grants Committee. Grants had been made during the past year to Drs. V. D. Harris, Noel Paton, W. D. Halliburton, Professor V. Horsley, Drs. A. Money, D. Williams, S. H. Martin, and T. Cash, Messrs. R. Stockman, G. A. Atkinson, Drs. Brown, W. Hunter, and P. M. Chapman. The Research Scholarships had been held by Mr. Watson Cheyne and Dr. A. Waller. Mr. Sibley said that the Association voted each year the sum of £600 for scientific research; of this sum £300 was given in divided grants to aid investigators, and the selection was made with great care. The other moiety was divided into two Research Scholarships—each tenable for two years.—Dr. CHADWICK seconded the motion, which was adopted.

Dr. NORMAN KERR moved the adoption of the report of the Habitual Drunkards Committee, and pointed out that the need for further legislation was imperative.—Dr. JACOB (Dublin) seconded the motion, which was carried.

Dr. BRIDGWATER moved the adoption of the report of the Collective Investigation Committee.—Mr. JONES MORRIS seconded the motion, which was carried.

On the motion of Sir B. W. FOSTER, seconded by Dr. B. O'CONNOR, an alteration in the bye-laws, proposed by Dr. Ward Cousins, and referred to the Council, relating to the representation of distinct branches, was put to the meeting and declared carried.

Sir W. FOSTER then moved the election as honorary members of Dr. N. S. Davis (Chicago), Dr. J. S. Billings (Washington), Dr. J. A. Grant (Ottawa), and Dr. W. H. Hingston (Montreal).—The motion was seconded by the PRESIDENT, and carried with applause.

Drs. DAVIS and HINGSTON briefly returned thanks.

The rest of the proceedings consisted in votes of thanks to the Mayor of Brighton for his hospitality and grand reception, moved by the PRESIDENT, seconded by Mr. WHEELHOUSE; to the Mayor and Corporation for the free use of the Royal Pavilion, Dome, and Corn Exchange, moved by Prof. GEIKIE (Toronto), seconded by D. W. STRANGE; to the President of the Association and members of the South-eastern Branch for their [illegible] reception on the 11th, moved by

Sir T. CRAWFORD, seconded by Dr. CUMING; to Sir Julian Goldsmid for his invitation to a garden party at St. Ann's-hills; to the managers of the New Club and the committee of the Sailing Club; to the directors of the Aquarium and West Pier; to Mr. E. T. Booth for permission to visit the Bird Museum; to Mr. Halliwell Phillips for his invitation to inspect his Shakesperian relics; to the Executive Committee; to the Duke of Norfolk and Lord and Lady Brassey for invitations to Arundel and Normanhurst.

Dr. CHADWICK proposed a vote of thanks to the President, which was seconded by Sir B. W. Foster and acknowledged by Dr. Withers Moore, who took occasion to correct the misapprehension of his address by his critics. His opinion was that woman had her special vocation, in which she was far superior to man. She was secure in her present position; she would not be secure if she tried to change it. He desired to express his deep sense of the kindness of the members of the Association.

THE SECTIONS.

MEDICINE.

The second meeting of this Section was held in the Music Room of the Royal Pavilion on Thursday, Aug. 12th. Dr. BROADBENT, President of the Section, delivered his address. The subject selected was the Remote Effects of Remedies. After referring to the well-known after-effects of alcohol, he alluded to the mental and bodily derangement induced by eating opium, the miserable irresolution and wretchedness of the man who habitually resorts to chloral, and the childish dementia brought on by the prolonged use of the bromides. He thought that coca is already beginning to claim its victims, who gradually develop an excitement which becomes maniacal or an exaltation like that of general paralysis. The subject of gout was given as illustrating the remote effect of remedies. The effect produced by continued and excessive use of colchicum and other drugs having a similar action, and the consequences following the neglect of such treatment which will clear the system of the gout poison, were especially drawn attention to. With reference to the latter he urged: "It can scarcely be too often repeated that all the effects upon the arteries on the one hand and the heart on the other associated with contracted granular kidney—viz, arterial degeneration, cerebral hæmorrhage, aneurysm and dilatation of the left ventricle, and valvular disease—are just as commonly produced independently of kidney disease by high pressure in the arterial system due to other causes; and such pressure in an extreme degree may be induced prematurely by the means taken to keep down gout." Another cause of injuriously high arterial tension was the "Banting" treatment of obesity as understood by the public. In this the non-nitrogenous sugars and starches were taken very sparingly—the amount of fluid taken into the system was reduced as much as possible, and the subject lived on a highly nitrogenous diet. The imperfectly oxidised nitrogenised waste present in the blood provoked resistance in the capillaries, and generated tension in the arteries. Exercise and an adequate supply of water, which were generally omitted, were essential to active metabolism and the working off of impurities. Another example of injury given was that furnished in asthma. Certain drugs afford alleviation of symptoms, but many popular powders contain powerful alkaloids, which produce after-effects on the nervous and vascular systems. "When we see the stupefied mental condition and the congested face and eyes, and note the large, weak, sluggish pulse, showing paralysis of the arterial walls, it is clear that such effects cannot be indefinitely repeated with impunity." "The right ventricle loses its tone like the muscular coats of the arteries, and, instead of becoming hypertrophied, yields to the resistance in the pulmonary circulation, and is dilated, finally giving rise to systemic venous stasis and dropsy." A striking illustration of his subject was given by the too careful and restricted diet of certain forms of so-called indigestion. One kind of food after another was left off, but still with the same discomfort and a sense of repletion after food. The appetite being wanting, a starvation point becomes almost reached. Instances of severe neuralgia, spurious attacks of angina pectoris, and serious debility, were related as having followed this line of treatment. Again, in the winter indigestion of women and weakly men, the functional energy of the stomach required stimulating by extra food, such as beef-tea, egg-flip, stimulants at meals, and tonics. What was wanted in winter indigestion was protection from the depressing influence of cold or the means of neutralising it.

A vote of thanks was accorded to the President for his address.

Dr. ORD followed with a paper on the Remote Effects of Gall-stones. In the discussion succeeding, Sir Peter Ede, Dr. Clifford Allbutt, and Professor Charcot took part. Papers on Mental Symptoms with Locomotor Ataxy, by Dr. SAVAGE; on Functional Albuminuria, by Dr. RALFE; and on the Relationship of Urea to certain Diseased Processes, by Dr. OLIVER, subsequently followed.

The third meeting of this Section was held on Friday, Aug. 13th. Dr. R. CROCKER demonstrated the Removal of Hair by Electrolysis. A paper was next contributed by Dr. MANTLE on the Etiology of Rheumatism, considered from a Bacterial point of view. Numerous specimens of micro-organisms found in acute and chronic rheumatism were shown. Inoculations had been made from the serum of joints and also from the blood taken under the usual antiseptic precautions. Cultivation shows bacilli having a peculiar mode of growth, preferring the surface and presenting a brown reticulated scum. The organism was said to grow best in an acid medium, and to stain well with Gram's method. These organisms had been found in over forty cases.—Dr. HAYCRAFT followed with two papers, the first with a demonstration on a New Method of Estimating Uric Acid, and the second on Some Points in the Coagulation of the Blood. Secretion from the leech was found to prevent coagulation, and when injected into animals produced temporary hæmophilia, for this bleeding continued from the smallest capillaries, but could be stopped by styptics such as perchloride of iron. There were also found extravasations within the body. This and other diseased conditions were thought to indicate that the coagulation of the blood was a necessary and temporary preventive of bleeding, so as to give time for the formation of new tissue. In hæmophilia, although time may be given for formation of healing tissue, bleeding may still continue, indicating probably diseased conditions of the connective tissue elements of the body. The author much desired specimens of hæmophilia blood, and the tissues of a wound preserved in alcohol. Other papers followed.

SURGERY.

On Thursday, Aug. 12th (Mr. Erichsen, F.R.S., President of the Section, in the chair), a series of papers on the Surgical Treatment of Hepatic Disease was read. The papers dealt less with general principles than with individual cases, and hence no adequate or satisfactory discussion took place. Dr. George Harley discussed and advocated hepatic phlebotomy and puncture in hypertrophic congestion. Mr. J. K. Thornton related some cases. Mr. Lawson Tait's contribution was by far the most important; this included seven cases of exploratory incision for a variety of conditions, including abscess, tumours of the liver and gall-bladder, and of cancer, with one death; thirteen cases of hepatotomy, chiefly for hydatids, without a death; and thirty cases of cholecystotomy, with three deaths. Mr. Willett related a case of cholecystotomy, and Mr. Howard Marsh a case of abscess of the liver opened by free incision. Mr. Adams read a paper on the Treatment of Congenital Displacement, so-called Congenital Dislocation, of the Hip-joint by long-continued recumbency and extension. The recumbency should not be less than one year, and might be continued under favourable circumstances for two years, or even longer. It was necessary to sustain the general health by horizontal gymnastics, &c. Mr. Ernst demonstrated a new and very ingenious extension couch, which he had constructed, at Mr. Adams's suggestion, for the effectual carrying out of this plan of treatment. Mr. Edmund Owen read a paper on Psoas Abscess, when and how to open it.

On Friday (13th inst.) what may truly be called *the* surgical paper of the meeting was read by Mr. VICTOR HORSLEY, entitled "Advances in the Surgery of the Central Nervous System." In introducing the subject, the author laid special weight on the fact that all the advantages, both scientific and operative, claimed in his paper were the results of lessons learned from experiments on monkeys. It had been said that monkeys were not quite like human beings, but this was not correct from a surgical standpoint. Time did not allow of any elaborate details, so the author contented

himself with a brief recapitulation of the chief facts of the case. He referred to (1) the preparation of the patient for the operation, which consisted in shaving the scalp, and then *thoroughly* cleansing the head; (2) anæsthesia—for this he preferred chloroform, previously giving subcutaneously a quarter of a grain of morphia; the morphia produced contraction of the arterioles of the brain, and there was consequently less oozing, and a less amount of chloroform sufficed; (3) strict Listerism, pure and simple—the spray was used, and the usual gauze dressings; (4) the line of incision—instead of the old-fashioned crucial flaps, a semilunar was advocated, as being easily displaced out of the way of the later steps in the operation, as less likely to suffer from interference with the blood circulation, and therefore with the vitality of the flap; (5) the use of large trephines—it was so difficult to hit the exact spot, and yet so necessary to have ample room, that the old small trephines were comparatively useless; (6) Macewen's plan of replacing the bone—the bone after removal was preserved in hot carbolised sponges, cut up into small pieces and placed in the opening between the dura mater and the scalp. The brain being exposed, the first question to decide was whether it bulged into the opening or not—normal brain, Mr. Horsley said, never bulges at first; if an operation lasted an hour or more some bulging became evident. If the brain bulged at first, it was presumptive evidence of the presence of a tumour; a yellowish colour and venous congestion were likewise suggestive points. The lesion being found, how was it to be treated? The use of the actual cautery led to secondary troubles, so he used a knife and excised what had to be removed, which must be all that was necessary, but not one bit more. There would doubtless be some considerable oozing at first; if so, a sponge should be pressed into the incision. The tumour or diseased part having been removed, it was desirable to close the wound as quickly and as accurately as possible; primary union of the skin flap was almost essential to success. Drainage was required for twenty-four hours only; if more serum collected, a small probe should be passed in to let it out, but a little tension did no harm, as it kept the brain matter in its place until cicatrisation was complete. Hernia cerebri only occurred as the result of decomposition. Mr. Horsley then demonstrated his three patients: they had quite recovered from the operation, and were well enough to travel to Brighton and be exhibited to the meeting. The main clinical symptoms were epileptiform fits, two of the cases following injury with subsequent scarring of the convolutions; the third case was one of tumour, which was accurately localised by the manner in which the fits (to which it gave rise) invariably commenced.

Professor CHARCOT (Paris) congratulated Mr. Horsley on his brilliant success. The patients, he said, might be taken (1) as new proofs of the value and legitimate use of animals for purposes of experimentation, and (2) as confirmation of the doctrines of localisation of the functions of the brain.

Dr. HUGHLINGS-JACKSON also congratulated the author on his admirable success. He thought that every person with epileptiform seizures was the subject of a very localised lesion of some kind, either a tumour or otherwise. If the aura were very localised and constant, it was in favour of tumour. He would, however, recommend an operation even if a tumour were not present. He had changed his views with regard to double optic neuritis, for tumours might exist without it. Mr. Horsley had produced artificially in monkeys fits similar to those from which these patients had been suffering, showing thus the accuracy of the present views on the function of the convolutions. He thought in removing the tumour that the adjoining portions of the brain ought to be removed, for the tumour produced fits by altering that portion of the brain on which it was seated. He would cut out too much rather than too little. Unfortunately there would occur cases with more than one tumour in the brain, or with more than one tumour on the same side of the brain.

Mr. HORSLEY then exhibited photographs, illuminated by limelight, of the parts of the brain injured and removed. A vote of thanks was carried by acclamation on its termination.

Dr. STEAVENSON and Mr. BRUCE CLARKE read papers on the employment of Electricity in the Treatment of Diseases of the Urinary Organs. Dr. Steavenson dealt chiefly with the scientific aspect of electrolysis, while Mr. Clarke referred to the practical side of the question.

The PRESIDENT remarked on the variety of the diseases referred to, and expressed himself unable to understand how one and the same remedy could favourably affect such diverse conditions.

Mr. VINCENT JACKSON also took part in the discussion, after which the authors suitably replied.

Mr. REGINALD HARRISON read a paper on the Treatment of Urethral Stricture by Internal and External Urethrotomy combined. He first entered into a consideration of the causes of relapse, the formation of cicatricial tissue, explaining his own views that this was largely increased by the passage of urine over the cut surface before it had had time to heal. Hence his argument was that after the stricture had been cut, an opening into the bladder through the perineum should be made simultaneously, by means of which the bladder could be efficiently drained; further, another tube should be passed from the perineum through the penis, in order to keep open the strictured part while cicatrisation was taking place.

Dr. PANCOAST (New York) advocated multiple incisions through the mucous membrane and submucous tissue, as giving better results than a single one.

Dr. WARD COUSINS and Mr. WHITEHEAD also took part in the discussion. Several ingenious urethrotomes were exhibited.

Papers were also read by Mr. F. CHURCHILL, on the Multiple Causation and the Immediate Treatment of Congenital Club-foot; by Sir WM. STOKES, on Acute Myxœdema following Thyroidectomy; by Mr. E. SMITH, on Obscure Disease of the Spine; by Mr. WHITEHEAD, on the Treatment of Hæmorrhoids by Excision, &c.

PATHOLOGY.

At the meeting of this Section on Thursday, Aug. 12th, Mr. T. HOLMES opened a discussion upon Aneurysm. The cause of aneurysm was defined as weakening of the vessel wall so that it yields to the blood-pressure. The change in the wall may be due to degeneration of coats, to laceration of the intima, to ulceration from without (of which an instance was mentioned). The degenerative changes include the atheromatous and syphilitic. There is no question that the subjects of aneurysm often have syphilis. Syphilitic subjects are generally persons broken down in health and liable to arterial disease. Syphilis affects arteries in two ways: either by thickening of the intima or by gummata in the external coats, thus rendering the vessel prone to aneurysm; but, practically, this seldom occurs. Heubner, in fifty cases of syphilitic arteritis, only found aneurysm in one. Again, the syphilitic process generally attacks the smaller arteries, atheroma the larger; the former leads to obliteration of the vessel, the latter to weakening and dilatation. Many cases of arterial disease in syphilitic subjects are alleged to be of a syphilitic nature, but there is often no direct proof of this. The true syphilitic degeneration of arteries rarely leads to aneurysm. The statistical argument is unreliable. Iodide of potassium, in Mr. Holmes's experience, is of little use in aneurysm, and certainly cannot owe its effect to its antisyphilitic action. Complete rest and careful diet are always beneficial, and in exceptional cases may effect a cure. The typical form of aneurysms produced by the giving way of one side of the vessel has been described by Syme as common to all aneurysms; but there are other forms—as fusiform &c.—where there is more than one opening. The relations between the vessel and aneurysm were illustrated by drawings—(1) single opening; (2) two openings at some distance from each other; and (3) where artery opens into and out of the aneurysm. The aneurysmal sac is a living tissue; the rapidity with which the sac sometimes shrinks must be due to vital changes, to which also are owing the alterations in shape. The treatment by introduction of foreign bodies or electrolysis is only applicable when nothing else can be applied, because of the risk of setting up inflammatory changes in the sac. Professor Loreta's case was mentioned, where the sac had contracted and consolidated after introduction of wire; death was due to rupture at the junction of the sac and vessel. Dr. Cayley and Mr. Hulke's case and Mr. Bryant's case were also mentioned. This form of cure (by impaction of clot) is also produced by Esmarch's bandage, the sac rapidly contracting. In manipulation the cure is sought almost wholly by impaction of clot; and the same thing occurs in rapid flexion. These methods have dangers of their own in injury to the walls of the sac. The absence of aneurysmal bruit is of evil augury, as showing there is no

proper mouth to the sac. The nature and direction of the growth of an aneurysm are of importance as indicating the line of treatment; this is especially seen in thoracic or innominate aneurysm pressing on the trachea or œsophagus. Cases were described where the detachment and impaction of clot at the mouth of the sac had given rise to coagulation within the sac, and these were contrasted with a case of distal ligature, when the same result ensued. There are cases, especially of aortic aneurysm, where danger may be due to growth of aneurysm in one or other direction, and where consolidation in these parts may be effected, and thus a partial cure with relief to symptoms obtained.

Mr. BARWELL agreed as to the non-syphilitic character of aneurysm, especially of the thoracic and abdominal varieties. He showed a specimen of aortic aneurysm, diagnosed as on the second part of the aorta, which projected on the left side of the sternum, having previously presented on the right. The patient was treated by rest, belladonna, &c.; but iodide of potassium increased his symptoms. Pressure on the root of the left lung was causing serious symptoms, and the patient begged that something might be done. An ivory cannula was introduced into the sac, and about 12 ft. of fine steel wire passed in, and an electric current was sent through the wire for seventy minutes. About four hours later the tumour began to consolidate. On the fourth day the saccule on the right side increased. Death took place partly from rupture of this sac and partly from the pressure by the main tumour on the root of the left lung. The wire was found to be completely covered with fibrine. In electrolysis, as a rule, the influence is not sufficiently diffused; and in introduction of wire the coagulum is too soft; a combination of the methods seemed to remedy these objections.

Mr. J. C. SYMONDS alluded to aneurysm due to external inflammation, mentioning a case which occurred in an amputated stump, which had become inflamed, and had led to softening of the vessel wall. He also mentioned a case where multiple aneurysm followed upon contusion of an artery, and the limb had to be amputated. In phthisis, pulmonary aneurysm owns a like cause. Probably secondary hæmorrhage from stumps is due to the same condition.

Dr. GOODRIDGE (Bath) read a paper on a case of large Abdominal Aneurysm in a man aged thirty-eight, who was attacked with severe pain in the left knee and swelling of the leg, extending afterwards to the thigh. A tense tumour occupied the left half of the abdomen; no bruit was audible. Six months previously he had been knocked down by a truck. After death, which occurred one month from the onset of symptoms, the tumour was found to be an aneurysm springing from the left side of the aorta, just above the bifurcation; it contained much clot and had eroded some of the lumbar vertebræ, and extended below Poupart's ligament, comprising the iliac vessels. It had ruptured into the peritoneal cavity, but by a very small opening; the fatal issue was also attended by pleural effusion.

Mr. HOLMES mentioned two cases of abdominal aneurysm which were unattended by the usual symptoms. One was a case under Sir P. Hewett, the tumour being diagnosed as a psoas abscess. The other was a case where there was fixed pain in the back; but after a time a tumour began to form; there was no bruit or pulsation. Death occurred suddenly, and a ruptured abdominal aneurysm was found.

The PRESIDENT (Dr. Dreschfeld) said the etiology of aneurysm is still very obscure; an atheromatous artery will withstand considerable strain. Again, aneurysm is very rare in Germany as compared with this country. As to treatment, one must not draw conclusions from a few successful cases. A case under Dr. Simpson was treated by electrolysis; after death it was found there were two aneurysms, one of which had been untreated and had undergone spontaneous cure; the other, which had been treated, still contained fluid blood. The introduction of wire was more likely to lead to consolidation. Fibrine ferment had been injected in one case at Manchester, but the clot formed was very firm and portions of it were wasted away and caused death by embolism.

Mr. BARWELL related a case of Upward Dislocation of the Sternal End of the Clavicle—a very rare form of injury. There was but little pain, and the movements of the arm were very slightly affected.

Dr. CHAFFEY read a paper upon Fibrinous Deposits within the Heart in Diphtheria and in some other diseases of children. The results of about 200 post-mortems on children dying from diseases of all kinds proved that out of fourteen cases of phthisis, four showed considerable fibrinous deposits, of which two were cystiform, whilst in the remaining ten cases fibrine was either absent or present in small amount. In tuberculosis (including tubercular meningitis, but excluding phthisis) three only, out of a total of thirty-three, presented fibrinous deposits of any size; very marked fatty changes in the muscular walls were present in two of these three cases. Of twenty-three post-mortems on diphtheria cases more than one-half showed marked fibrinous deposits. They were situated chiefly in the right cavities, though to some extent the left cavities suffered also in most cases. In seven of the twenty-three, the right cavities were nearly filled with firm decolorised fibrine. A few other cases presented well-marked fibrinous deposits—viz., two of morbus coxæ, where death resulted a few days after amputation at the hip-joint; one case of osteotomy of the femora; one of tracheotomy for papilloma of the larynx; one case of acute and two of chronic tubular nephritis; two out of seven cases of diphtheritic paralysis; and one case each of simple purulent meningitis, otitis with pneumonia, pyelo-nephritis, and diabetes mellitus. There were also two cases of morbus cordis with old fibrinous deposit, and one of adherent pericardium with softening fibrinous deposit in the right auricular appendix giving rise to pneumonia. (Mounted specimens were shown illustrating deposits of fibrine, some of which almost filled the right cavities of the heart.)

Dr. COUPLAND confirmed, from his experience, the comparative frequency of cardiac thrombosis in diphtheria, to which cause was often owing the sudden death, frequently attributed to cardiac paralysis, which occurred in diphtheria. It mostly happened after the local diphtheritic symptoms had passed away, and was due, as Dr. Chaffey said, to weakening of the heart walls by fatty degeneration, and sometimes to interstitial myocarditis, as in a case under Dr. Coupland's care. Leyden had described diphtheritic myocarditis, and detected micrococci in the inflammatory exudation.

Dr. WOODHEAD (Edinburgh) said that these coagula occur in very many conditions in children, especially on the right side of the heart. They are not uncommon in specific inflammatory conditions, as in scarlet fever, tubercle, and in catarrhal pneumonia. There is almost invariably cloudy swelling, or interstitial inflammation, or fatty degeneration. This coagulation commences on the right side and afterwards occurs in the left cavities.

The PRESIDENT confirmed what had been said, remarking that acute dilatation of the heart, due to inflammatory or degenerative changes, was a frequent result of specific poisons. Venesection should be tried in these cases of acute thrombosis, especially in adults.

At the meeting of this Section on Friday, August 13th, Dr. STURGES opened a discussion upon the Etiology of Pneumonia. He said that in the course of an inquiry into the subject by the Collective Investigation Committee, the opinion of a large body of the profession was obtained. The pneumonia in question was that form of acute lobar pneumonia occurring suddenly, running a short definite course, and with recovery in the large majority of cases, which is a disease *within* the lung rather than *of* the lung. Therefore the idea gained from post-mortem inspection is incomplete. The causes of pneumonia are now admitted to be more numerous than supposed by former authorites. There is nothing more instructive or striking than an attack of the malady to which there is no parallel in other forms of disease. There has been a prevalence of pneumonia during the past spring, which has been characterised by exceptional weather—prolonged cold and easterly winds; when the milder weather came then pneumonia became less frequent, so that pneumonia was "caught" and prevailed like ordinary catarrh. This is the most frequent form of acute lobar pneumonia due to chill, a form which by adopting modern theories we are apt to forget. There is the pneumonia of alcholic excess, which post mortem is the same as that due to chill. Does chill play any part at all in such a case? The patient may not be exposed to chill, and the conclusion is that alcohol is as much a cause of pneumonia as chill. Again, there is sufficient evidence that "sewer-gas poisoning" causes pneumonia, and in many cases totally apart from the prevalence of cold weather. Besides the alcoholic and pythogenic form, there is another, which is preceded for some time by ill-defined symptoms of gastro-intestinal disorder, especially in children, the acute

pneumonia being, as it were, the final effect of the poison, much as in gout a period of deranged health will culminate in an attack of acute gout. There is a near connexion between privation and pneumonia, and that apart from exposure and alcohol—e.g., in the Madras famine one in five died from pneumonia. Over-work, fatigue, and mental depression favour the advent of pneumonia, and such cases have a gravity special to themselves. So that pneumonia as a local disease must be replaced by the notion that it is only part of a wider disorder. It may be that in rare instances pneumonia, like diphtheria, takes on contagious characters—a recent paper by Dr. Bruce confirms this strongly—by the occurrence in families and the presence of micro-organisms. Dr. Bruce admits that this infection is rare, and epidemic prevalence is not proof of infection. If pneumonia be conveyable from person to person, it ought to show itself in hospital wards; but Dr. Sturges cannot find a single instance of this. There is less positive evidence of contagion as a cause than of the others enumerated; and is it necessary ever to involve contagion to explain the disease? In a family there is not only a general tendency, but there are added fatigue, mental depression, and often exposure by the graveside—all causes which may explain multiple pneumonia in families, apart from any epidemic influence. The points he raised for discussion were—What are the exciting causes of simple pneumonia? Is there any evidence of the conveyance of the disease from one to another? How are predisposing distinguished from exciting causes? and what is the proper place of this idiopathic pneumonia in nosology.

Dr. DOUGLAS POWELL in most points agreed with Dr. Sturges. Some would say that the causes of pneumonia, instead of being more numerous, are now reduced to one—viz., the introduction of the pneumococcus—no matter whether the individual be subjected to chill, alcoholism, &c. No one familiar with Friedländer's researches can doubt for a moment the existence of an organism in all cases of pneumonia, which can be cultivated and reintroduced into certain animals, which thereby become attacked with pneumonia. In a series of eighteen consecutive cases of pneumonia recently observed, Mr. Leopold Hudson had examined the sputa, and in every instance had found this micro-organism. [Photographs by Mr. Crookshank and specimens of cultures were shown.] Most of these cases were typical ones, but not all. One was an apex case in a drunkard; in another the pneumonia supervened in chronic lung-disease. In another patient, after an obscure illness of twenty-one days before admission, the signs of pneumonia developed; and, lastly, there was a case of a girl who was attacked after exposure to cold, the course of the disease being marked by hectic, and now passing into phthisis, although the bacillus tuberculosis had not yet been detected. In all these varieties the coccus was present, so that in what clinically are regarded as different forms the characteristic micro-organism is to be found. Any hope that one might have of distinguishing septic cases by this test is therefore disappointed. Is it possible that these organisms are of different kinds? The researches into micro-organisms of pneumonia have been too uniformly successful for them to be the cause of the disease. Evidence is accumulating which tends to show that we are teeming with organisms, and that when certain diseases arise a kind of culture goes on of what are as yet indifferent organisms which converts them into specific forms, which may propagate the disease. He would therefore regard these organisms as rather epiphytic than as truly pathogenic or causative.

Dr. CHURTON (Leeds) had in post-mortem examination found pulmonary œdema very common, but had only twice met with distinct evidence of pneumonic exudation in such cases, where, as a rule, the alveolar walls look perfectly healthy. Whatever be the cause of pneumonia, the products are the same, and it would be inconceivable that only one cause should produce this result. The damaged lung may be the soil in which the pneumococci thrive, and they in their turn irritate the tissue, giving rise to inflammatory exudation. Pulmonary œdema is always most marked in the upper lobe. He would admit as exciting causes of pneumonia not only the pneumococcus but many other causes; and it is difficult to explain the selection of one part of the lung rather than another. As to contagion, Dr. Churton had never seen pneumonia spread in a hospital ward, or even in the most ill-ventilated apartments. The prognosis depends on the condition of the patient before he is attacked.

Dr. HOLLIS (Brighton) said that if the pneumococcus is invariably present, it more or less decides the matter as regards the exciting cause. If it be hereafter shown that in the pneumonia of typhoid fever, or in that which occurs by extension from other parts, the pneumococcus occurs, he would suppose it to be the active cause. As to the clinical conditions, we have to treat different forms of the disease.

Surgeon-Major BLACK gave his experience in the army. Sometimes the pneumonia would run through a regiment after fatigue, chill, and exposure; and yet such cases were quite unconnected with infection. He also cited cases of pneumonia due to insufficient clothing and chilling, with inactive circulation, as in people who sit in public gardens listening to music on chilly evenings, and too lightly clad. He therefore thought it indisputable that pneumonia could be directly produced by chilling of the surface of the body.

Dr. COUPLAND remarked that since the pneumococcus had answered to the tests required to establish its pathogenic character, the whole question of the precise relations of bacteria to specific diseases must depend on the solution of the problem as regards pneumonia. Moreover, the clinical course of acute lobar pneumonia was very much allied to that exhibited by other specific diseases which are now equally claimed to be bacterial: e.g., facial erysipelas—a disease, too, which prevails under meteorological conditions similar to those under which pneumonia prevails. It may well be that the true solution is that in all bacterial diseases the microbes are, as Dr. Powell suggested, epiphytic, but yet specific and characteristic of the disease.

Dr. MAGUIRE had exhibited at Belfast the pneumococcus not only in the lung but in other organs—as spleen, kidney, &c. In the case of all germs one must consider the concomitant conditions. Undoubtedly cold has some influence in producing pneumonia. When he was pathologist at the Manchester Infirmary there were epidemics of pneumonia and fatal cases, especially in certain months of the year. At the same time, it is absolutely certain that there is a microbe in the pneumonic lung which differs from others, and it is probable that we might trace its life-history a little further. The mere morphological characters of a germ are of no use in determining specific differences; the physiological properties must also be considered.

The PRESIDENT (Dr. Dreschfeld) said that there does exist an organism in some forms of pneumonia, one which can reproduce the disease after culture and inoculation, there is very little doubt, although it may not be present in all forms. It is impossible to recognise as a pathological entity the pneumococcus found in sputum. If the same pneumococcus be found in the lung and cultivated, &c., it must have something to do with the disease. That a contagious pneumonia exists is proved beyond doubt; and there is the type known clinically as "creeping pneumonia," where the inflammation spreads gradually from one part of the lung to another. In Manchester, lately, this form of contagious pneumonia prevailed with well-marked characteristics. In these cases the pneumococcus was found and cultivated, and inoculations made by Friedländer from these cultures produced pneumonia in guinea-pigs, but not in rabbits. One is compelled to admit modified forms of pneumococcus to explain these different forms of disease. Indeed more than one kind of pneumococcus has been found. Besides Friedländer's, there is that described by Fraenkel, which can infect rabbits but not guinea-pigs; and a third variety has also been met with. If there be such differences in the microbes, it is easy to explain clinical differences. Recently a pneumococcus has been found in catarrhal pneumonia. Again, the same anatomical lesion may be produced by different causes, and no doubt there are many predisposing causes.

Drs. STURGES and POWELL replied briefly.

Dr. W. A. HOLLIS read a paper on Pulmonary Tuberculosis associated with Heart Disease. The author gave brief notes of three cases of heart disease associated with tubercle of the lungs. In every instance the heart disease preceded the phthisical symptoms. The cardiac complications, which were various, resembled each other, inasmuch as they were invariably accompanied with dilatation, of the right chambers especially. Dr. Hollis conjectures that, as the cubic expansion is three times the linear, the contractile energy of a dilated ventricle will speedily prove inadequate to propel its liquid contents through the vessels, even when its strength is supplemented by considerable compensatory hypertrophy of the walls. In such cases the heart at each contraction only forwards a portion of the contained blood

at each systole, and it therefore necessarily acts as a reservoir for the residuum. This condition of the circulation leads to anæmia and consequent malnutrition of the body generally—a state which was observable in all the cases narrated. The lungs will especially suffer under these circumstances, and will possibly offer a favourable nidus for the growth and development of tubercle bacilli, which were discovered in the sputum of one of the narrated cases.

PUBLIC MEDICINE.

On Wednesday, August 11th, after the introductory address by the President, Dr. Taaffe, Deputy-Surgeon JOSEPH EWART opened a discussion on Scarlet Fever, its causation, and the best sanitary measures for dealing with the disease as it exists among urban populations. He said that scarlet fever accounts for a twentieth or twenty-fifth of the general death-rate; it occurs among all classes, but is mainly a disease of early life. Its infectious character is based on the clearest evidence; it is often difficult to trace the origin of the first case, but there is no doubt as to the manner of its spread afterwards. The prompt removal of a case of scarlet fever prior to the development of its infecting property is sure to prevent its communication to others; immunity is also obtained by the thorough disinfection of tainted articles. The speaker then proceeded to show that the *materies morbi* appears in the juices of the skin, in the exfoliated cuticle, nasal and pharyngeal exudation, the breath, probably at certain stages in the renal secretion, and possibly in the alvine excreta. After describing the means by which the disease is disseminated, Dr. Ewart discussed the incubation period, which he stated to be usually from two to five days, occasionally not more than twenty-four hours or even twelve or fourteen days. He considered it rarely communicable during incubation, but infectiousness lasted from the commencement of the eruption up to the completion of the peeling process. Imperfect ventilation and overcrowding increase the liability to this disease. To prevent its spread the first essential condition of prophylaxis is segregation of the affected from the unaffected and continued isolation of the sick; the detailed arrangements were indicated as well as those of disinfection, and the speaker urged the need for all hospitals being provided with isolation wards and of special hospitals for the reception of those who could not be properly isolated in their own homes. But their use is not to be regarded as sufficient substitution for sanitation and hygiene. Notification was pleaded for, and this subject was briefly discussed as well as that of compulsory removal. Dr. Ewart, while expressing his sense of the value of these methods of prevention, doubted whether the compulsory removal of cases would receive the cordial assent of the public at the present time.

Dr. WILLIAM SQUIRE expressed the opinion that the improved sanitary condition of a town had never led to any difference between the incidence of scarlet fever upon the rich and the poor, those surrounded by the best circumstances and the most healthy suffering as severely as others. With reference to the subject of notification of infectious disease, he thought medical men would raise no objection. Hospitals for the isolation of persons suffering from this class of malady should be situated near to where the patients lived; he had never known scarlet fever spread from an invaded house to another on the opposite side of the street.

Dr. GRIMSHAW considered that the most important means of preventing the spread of scarlet fever was, in the first place, notification of the disease, and the isolation of the patient must follow.

Mr. BUTTERFIELD observed that his experience was that the worst cases of scarlet fever did not occur amongst poor persons. Notification was of no use until the means for isolation had been provided. In Bradford he had met with no difficulties in the enforcement of the provisions of the local Notification Act.

Mr. VACHER held that powers of compulsory removal of infectious cases were urgently needed. At Warrington, where this power existed, 90 per cent. were removed to hospital. Still, much could be done without such power, as at Salford, where 50 per cent. of the cases were removed.

Dr. TAAFFE, after speaking in favour of the Nottingham system, where the medical man notifies to the householder and the householder to the sanitary authority, urged the need of provision for isolation of persons in all classes of life.

The discussion was continued by Drs. Groves, Norman March, the Rev. Kerr, Sykes, Duncan, Bird, and Surgeon-Major Evatt and Mr. Brown.

Mr. BOOBBYER read an interesting paper on two outbreaks of scarlet fever which occurred concurrently with the disturbance of impure subsoil, to which we hope to refer later.

The proceedings terminated with a paper by Surgeon-Major PRINGLE, on the Advantages and Disadvantages of Human and Animal Lymph. He pointed out that his object in making this comparison was that, judging from the report of the German Vaccination Commission, published in 1885, and very carefully condensed by Dr. E. J. Edwardes, the preference, as given by this very important commission was undoubtedly in favour of animal lymph. The necessity advanced by the opponents of human lymph for the substitution of animal for human lymph was based on the following four objections:—1. The supposed deficiency in the protective power of human lymph, owing to some unaccountable deterioration in this principle, caused by the passage of the virus through the systems of so many individuals. 2. The danger to health and life, owing to the possible introduction into the system of syphilis or the infection of erysipelas. 3. The difficulty of obtaining sufficient human lymph for any sudden emergency or great demand. 4. The general objection raised to the withdrawal of lymph for other operations. Animal lymph, the speaker said, was supposed to overcome these four objections, as follows:—1. Animal lymph could never become deficient in protective power, owing to its constant reinvigoration from the calf. 2. The dangers to health and life, owing to the possible introduction into the system with human lymph of syphilis and the infection of erysipelas, could not occur where animal lymph was employed. 3. As long as suitable calves were obtainable, it was maintained that the supply of animal lymph, to meet any emergency or great demand, was inexhaustible. 4. For the same reason, no possible objection could be raised under this point. Dr. Pringle then met the four objections brought forward against human lymph. 1. The objection under the head of deficiency of protective power. In Dr. Pringle's extensive and prolonged vaccine practice in India, details of which he gave, he maintained that, where carefully and systematically practised by arm-to-arm vaccination, this deterioration was unknown, and this was certainly not due to the absence of small-pox contagion or infection. 2. There was a complete absence in the above practice of any risk as regards syphilitic transference, and the infection of erysipelas was unknown. 3. With a properly instructed vaccine staff this limited supply of human lymph was unknown, and where the number of children was small the knowledge of storing lymph prevented any difficulties under this head. 4. Mutual confidence between the vaccinator and the parents of the children would satisfactorily overcome any difficulty regarding the withdrawal of lymph for future operations. Dr. Pringle argued against the view that animal lymph was more protective than humanised, and quoted an official report in support of the view that a spurious vaccination could exist for years. Further, that blood poisoning, although not of a syphilitic character, might follow the use of animal as well as humanised lymph, that animal lymph was incapable of storage or despatch with any certainty, and that unless squeezed out with clamps and forceps the contents of six vesicles would only supply sufficient material for the inoculation of one person.

On Thursday, Aug. 12th, Dr. GAMGEE, F.R.S., on behalf of Dr. Ransome of Manchester, who was unavoidably absent, read a paper on the Duration of Infectiousness of Scarlet Fever, Small-pox, Measles, Mumps, and Diphtheria, and pointed out the need for more precise information on this subject. He suggested that the Association should appoint registrars throughout the country who should investigate every case which came to their knowledge, and obtain, when necessary, detailed information from medical men and even the patients themselves, so as to avoid all source of error.

The discussion was continued by Drs. PRINGLE and HOPE, the latter defining the infectious period of measles to extend from the second day of the symptoms and to last for three weeks; of small-pox, from the first day of the symptoms to from three to four weeks; scarlet fever, from the fourth day, and to last seven weeks; mumps to be under three weeks; and diphtheria to be the same.

Dr. C. KELLY read a paper on the Relation of Soil to Diphtheria. It was shown that in England the death-rate from this disease was the lowest of the four common diseases of childhood, while in some parts of Sussex the mortality from

diphtheria was higher than from measles, scarlet fever, and whooping-cough added together. This prevalence was coincident with wet, retentive soils. On the dry and pervious formations, the death-rate over a period of ten years was only 127 per million persons living, while on the cold, wet soils the mortality was 454 per million. This great increase was not met with in large towns or in populous places, where inter-communication among children is very frequent; but it was most marked in lonely, isolated places, where the children had to go a long way to school and were exposed to conditions of cold and wet. In urban districts no similar outbreaks were met with, and in such cases the disease seldom spread, and it was apparently due to sanitary defects. The disease constantly appeared in rural districts in the autumn of the year, causing primary outbreaks.

Dr. PARSONS agreed generally with Dr. Kelly's conclusions except as to the relation of diphtheria to damp soils; he himself had noticed endemic prevalence of this disease on high and dry soils, and indeed on all kinds of soils. He dwelt upon the special prevalence of diphtheria in rural as compared with urban districts, and quoted statistics in proof of this fact. Diphtheria, he thought, was spread by personal communication, but in towns usually some sanitary defect was found in the houses where it occurred, but this was not so in the country. He suggested that the freedom of towns might be explained if the disease were due to some fungoid growth which could not thrive in an atmosphere of coal-smoke; on the Continent, where coal is not largely consumed, towns are not more exempt than country districts.

Dr. WILSON, of Doncaster, observed that while the deaths from zymotic diseases generally were decreasing, those from diphtheria were increasing.

Dr. SQUIRE called attention to the fact that clay soil occupied a much larger extent than other soils, and this, he thought, might account for the greater prevalence of diphtheria thereon.

Dr. GROVES thought there was a relation between the prevalence of diphtheria in a district and antecedent scarlet fever; he noted the tendency of these diseases to appear in wooded districts.

Dr. KELLY, in conclusion, raised the question whether the diphtheria of the towns was absolutely identical with that of the country districts.

Surgeon-Major EVATT gave an address on the Medical Department of an Army Corps in War. He said an army corps in war time consists of 36,000 men; this is divided into three parts of 10,000 men each, with a cavalry brigade and artillery. To each regiment is attached one medical officer, and he has given him two to four men per company. Their duties are to give first aid to the wounded, who then pass into the hands of the divisional bearer companies of the medical staff corps, with all necessary appliances, waggons, &c. The wounded may be operated on at this stage and subsequently transferred to the field hospitals, of which there are in each army corps fourteen for one army corps. Thence the wounded pass to the base hospital, the organisation of which was described, and thence in the ship hospitals to England. Dr. Evatt pointed out that what is now needed is a Volunteer medical staff corps sufficient to supply divisional bearer companies and field hospitals in the same way for the Volunteer forces, which are now 250,000 strong.

Dr. BILLING gave an account of the difficulties with which the army surgeon had to contend during the American war, and Mr. WALTER PEARSE stated that steps were now being taken to improve the medical service in connexion with the Volunteers.

Dr. TATHAM (Salford) read a paper on the best means of dealing prophylactically with Scarlet Fever in urban populations. It appears that in past years Salford has occupied a prominent position amongst the scarlet fever fields of England, the average annual rate of mortality from this disease in the twenty years ending in 1875 being equal to 135 per 100,000 of the population; but that under the combined systems of compulsory notification and hospital isolation obtaining in the borough during the last few years scarlatina mortality has been reduced to an average rate of 50 per 100,000. Dr. Tatham gave interesting particulars of the steps taken in Salford for the stamping-out of scarlet fever, vigorously insisting that in order to exercise reasonably sufficient control over its spread, it was essential that sanitary authorities should possess powers for securing immediate notification as to all scarlatinal attacks.

At the conclusion of a discussion which followed the reading of the paper, the subjoined resolution, proposed by Dr. TATHAM and seconded by Dr. GRIMSHAW, the Irish Registrar-General, was carried:—"That the Public Health Section of the British Medical Association, having considered the papers read and the remarks made upon them, are of opinion that the time has arrived when the protection afforded under the Act for the compulsory notification of infectious diseases should be extended to the population generally, and they recommend the Council to consider at an early date the advisability of endeavouring to promote general legislation with this object in view."

Preliminary to the adoption of this resolution, Dr. WHITELEGGE showed a marked reduction in deaths from scarlet fever in Nottingham subsequent to the passing of a Notification Act. Diphtheria, which had only recently been added to the list of diseases to be notified, had only declined since that time.

Dr. H. ASHBY read a paper on the Duration of Infectiousness in Scarlet Fever, and urged the necessity for seaside towns who wished to preserve their reputation as health-resorts to take special precautions.

Dr. NORMAN KERR read a paper on Hydrophobia, in which he gave the history of the disease, and stated that it was known to Aristotle. Referring to Pasteur's work, he considered that he had been more successful than any other person; Dr. Kerr expressed the opinion that all dogs should be muzzled and stray dogs destroyed.

Mr. C. E. PAGET followed with a paper on the Influence of Acute, supposed Simple, Sore-throat in the spread of Diphtheria. This paper contained descriptions of two epidemics of diphtheria which occurred in and around two villages widely separated from each other during the months of September, October, and November, 1885. Both of the outbreaks were characterised by the mildness of the large majority of the cases that occurred, and in one this feature was so masked that the nature of the prevalent throat illness had never been suspected until the close of the outbreak, when a severe case of true diphtheria came to light. That the doubtful cases of past and present throat illness in the two epidemics, which the writer at the time of investigation was able to collect together, were cases of "mild" or "benign" diphtheria, though they were not followed by paralytic sequelæ, was rendered probable, (1) because one of the results of investigation was the disclosure of the fact that these cases had occurred in close precedence of true cases of diphtheria; (2) because other cases of throat illness as mild, which followed them in both epidemics, were found to have been cases of diphtheria; and (3) because there is at present not evidence enough to support a theory that a single simple case of sore-throat can give rise to a case of diphtheria. The paper concluded with an explanation that such epidemics can occur so easily and so extensively in rural districts, chiefly because medical men are necessarily few in number, and the labouring classes are not in the habit of seeking medical aid in mild cases of illness.

The meeting concluded with a paper by Surgeon-General CORNISH on an Outbreak of Cholera among British Emigrants on board a vessel proceeding from London to Queensland in the latter part of last year.

On Friday, August 13th, Dr. MICHAEL W. TAYLOR (late of Penrith) read a paper on Diphtheria in connexion with Mould Fungi. The purpose was to work out a certain hypothesis, which, stated in its simplest form, was this: that the spores of some common moulds under certain conditions are capable of originating diphtheria. He now brought forward the whole evidence from his personal clinical experience in support of these views. The cases disclosed some curious, exceptional, and unique features in their history, comprising observations in seven different outbreaks of diphtheria, amounting to sixteen attacks and two deaths. In one series of cases the growth of aspergillus associated with a pileate fungus a coprinus, on the walls of a bedroom, was given as determining the incidence of the disease. In another case the development of common moulds in a damp house, within which a large quantity of recent cat-skins were stored, seemed the most probable source of a fatal case of diphtheria. In another instance a young man took diphtheria severely four days after working all day in a pigeon garret which was full of mould from the débris and rotten woodwork. Three outbreaks of diphtheria were traced to the sufferers having occupied rooms in which a large quantity of sheep's wool had been stored. Dr. Taylor regarded the incidence and sequence of events as affording strong [illegible] these cases that circumstances

arising from this wool storage were primary causes of these outbreaks. He continued the argument that diphtheria is due to the action of micro-organisms; that analogous parasitic diseases are produced by organisms morphologically identical with common moulds; that there may be alternations of development and transformations of innocuous organisms into pathogenic forms; that this may be the result of growth in noxious media; that the infective element may be a virus elaborated in the protoplasm of the organism derived from the media or a living host, and, along with the germ, capable of being multiplied in living structures.

Dr. CHARLES DRYSDALE read a paper on Animal Vaccination. He had, in a paper read before the Medical Society of London, strongly recommended the substitution of the process of calf-lymph vaccination to replace vaccination with long-humanised lymph now in use in this country. Many countries, such as Holland, the United States, &c., had at this moment practically abandoned humanised lymph, using calf lymph alone. Dr. Drysdale said he had always held that vaccination was merely mitigated small-pox, and that the reason why it protected against an attack of small-pox was that it was merely a slighter form of the same disease. If, then, vaccinia were mitigated small-pox, it was not probable that when transplanted to man it would remain long unchanged, and statistics seemed to show that long-humanised lymph had lost much of its power in preventing variola. Dr. Charles Cameron (*Fortnightly Review*, 1881) mentioned that the number of small-pox cases in 1000 vaccinated was very much greater of late years than formerly, and that the death-rate had increased from 1·75 per cent. between 1819 and 1835 to over 10 per cent. in 1870-79. On the other hand, the late Dr. Henry Martin, of Boston, U.S.A., had alleged most distinctly that up to the date when he attended the Ryde Congress of the British Medical Association, the calf-lymph vesicle had not in any way deteriorated or lost its preservative powers. According, too, to that most energetic of all modern vaccinators, who succeeded in banishing the use of humanised lymph from his adopted country, the United States, the case of animal vaccination was a complete preventive against small-pox, and also quite free from the reproach of causing erysipelas. Dr. Warlomont, of Brussels, also mentioned that, in the epidemic of 1870-71 in Brussels, those patients who had been vaccinated with calf lymph entirely escaped small-pox; and Dr. Martin gave instances where in one epidemic of small-pox in San Francisco humanised lymph had proved of little efficacy, whilst animal vaccine in a subsequent epidemic had entirely prevented the occurrence of small-pox. Dr. Drysdale thought the only conclusion must be that vaccine should always be drawn from the calf, and moved the following resolution:—"That this meeting, after taking into consideration the superior advantages of animal vaccination over long-humanised lymph as acknowledged in the United States and other countries, such as Holland and Prussia, recommends the substitution of vaccination by calf lymph for the present system of arm-to-arm vaccination, and the discontinuance of the practice of arm-to-arm vaccination in this country."

Mr. J. BRINDLEY JAMES seconded Dr. Drysdale's motion.

Mr. SHIRLEY MURPHY and Dr. WILLIAM SQUIRE urged the advantage of arm-to-arm vaccination over any system that would necessitate the use of stored lymph, and opposed the motion.

After further discussion an amendment was adopted in favour of arm-to-arm vaccination, but expressing the opinion that greater opportunities should be given for direct vaccination from the calf.

Dr. J. GROVES read a paper on the Sanitary Acts as applied to Rural Sanitary Districts. He said the rural sanitary district is not what its name would imply, a purely agricultural area, but one containing old and new towns and parts of large towns and cities which possess urban government and which have overflowed the civic boundaries. The suburbs of towns will increasingly extend into the rural districts about them. The powers and obligations of rural authorities should therefore be commensurate with their responsibilities. The Rivers Pollution Act, 1876, applies fully to rural sanitary districts, and the rural authorities can by it prevent even the pollution of the sea under certain circumstances. The Public Health Act, 1875, contains enactments which are common to both urban and rural districts, or which apply to one or other exclusively. Section 91, which applies to both, is the most effective possessed by rural sanitary authorities for abatement of the most dangerous nuisances. The test of the value of a sanitary law is the celerity with which it can be used. It takes about six weeks to bring into and enforce in a court of law Section 91. A similar nuisance in the next street under urban rule can, and in many cases must, be abated by the authority, under Section 47, which belongs to urban authorities exclusively. Offensive trades can only be dealt with as nuisances under Section 91 by rural authorities, and it is most difficult to obtain a conviction; while urban authorities can deal with them successfully under Sections 112 and 114. Dangerous and dilapidated buildings, dealt with by urban authorities under Section 160, cannot be dealt with at all by rural authorities. Although nearly all the new houses are being built in the rural districts, in many parts rural authorities have not the least control over their construction or over the construction of wells or cesspits. Section 276 enables rural authorities to apply to the Local Government Board for urban powers, but as the section is permissive it is comparatively valueless. Many rural authorities will not accept urban powers or make bye-laws. The Public Health (Water) Act, 1878, would have more value if it contained a definition of what constitutes wholesome water. The continued wholesomeness of water depends upon the surroundings of the supply rather than upon the existence of a small amount of organic matter in it at a given moment. The Sanitary Acts enable rural sanitary authorities to deal only with what is at the time present. They cannot require precautions to be taken for security of the public health. The time has come for revising the Public Health Act, 1875, as it applies both to urban and to rural authorities, but in rural districts it is imperative that action should be taken forthwith. Certain sections of the Act of 1875—as Secs. 47, 49, 112, 114, and 160—should be at once made universally applicable, and rural authorities should be required to frame bye-laws, and especially such building bye-laws as would give fair security against disease. To this end it is desirable that the Local Government Board should frame a second set of simple model bye-laws especially applicable to rural districts.

OTOLOGY.

MR. HODGSON, the President of the Section, selected as the subject of his address the Progress of Aural Surgery during the Present Century, and, after offering a welcome to the visitors, remarked that the period of eighty years includes the history of about all that can be recorded on the subject to any purpose; as although the anatomy of the organ of hearing had been fairly well made out for a century or more previously, a knowledge of its diseases and their suitable treatment could not be said to exist: what was thought and done was not only devoid of common sense, but for the most part empirical, not to say absurd, and sometimes even disgusting. In 1806 a Mr. John Cunningham Saunders (demonstrator of practical anatomy at St. Thomas's Hospital) brought out the first book of English origin that put aural surgery on a clear and sound footing. He classified the diseases as they respectively affect the outer, middle, and internal portions of the organ; and although his means of diagnosis were very defective, yet by making numerous careful dissections of the ears of deceased persons who had been deaf, he obtained valuable information wherewith to guide his notions of pathology and treatment. He pretty successfully treated otorrhœa and polypus, practised paracentesis of the membrane for tympanal suppuration, and showed that neglected suppuration of the ear might lead to brain disease. Some six years previously Mr. Cooper (afterwards Sir Astley) had, at the suggestion of Sir Everard Home, punctured the membrane in a few cases in which the Eustachian tube was supposed to be impervious, with the object of letting air into the drum cavity. Some thirty years afterwards, Kramer of Berlin, and two years later Pilcher of London, each brought out a book on diseases of the ear. Both these authors dwelt much on the importance of Eustachian treatment; Kramer by means of the catheter and a metallic air-pump for forcing in air and vapours to the tympanum, and Pilcher by using bougies and stilettes and sending in fluid injections by the catheter and a syringe. Kramer's treatise held sway for many years; although his air-pump soon fell into disuse in England, especially after the occurrence in London of two sudden deaths during its employment by a practitioner in Gower-street. Emphysema of the throat, implicating the glottis, was supposed to be

the effect, the mucous membrane having been torn first by the point of the catheter. A case of emphysema of the neck, whilst using the catheter and air-pump occurred to Pilcher, but it did not prove fatal. In 1848, in THE LANCET for July 1st, Mr. Yearsley made public his fortunate discovery of the so-called "cotton-wool drum," the value of which is still considered as great as then. If Saunders had lived longer one can imagine that he might have hit upon something of the sort, as he seems to have been much struck with the fact that one or two of his patients heard considerably better whilst a drop or two of fluid (even if it were pus) was in contact with the maimed membrane. During the decade 1850 to 1860, Wilde of Dublin and Toynbee of London came to the front, the former advancing aural surgery in a thoroughly practical and common-sense manner. The polypus snare, a free incision down to the mastoid process, and the tubular speculum are identified with his name—the speculum, however, being modified from Gruber's, and perhaps not thereby improved. Toynbee, by his painstaking and indefatigable dissections, put the pathological anatomy of the ear on a footing never previously approached, and which has largely helped forward a more correct understanding on the subject. In consequence of Toynbee having drawn attention to the normal condition of the Eustachian tube being *closure* (except under the influence of some muscular action, such as swallowing), Politzer was led to work out his simple and now well-known method of inflating the drum cavity. The name of Politzer, Mr. Hodgson observed, brings us to within a quarter of a century of the present day. During this period increased activity has sprung up, most civilised countries having furnished men who have made advances in otological knowledge. Thus, Lucæ and Politzer have taught us the use of the tuning-fork; trephining the mastoid (which Petit originated in 1774) has been revived by Troltsch, James Hinton, and some Americans, and been fully established as an orthodox proceeding. Troltsch again has given us a simple, but effectual, mode of illuminating the meatus and the drum membrane; and the laryngoscope, reversed, serves as well for examining the pharynx and posterior nares; whilst, during the same space of time, numerous books and monographs have appeared, wherein not only the minuter anatomy (healthy and morbid) and physiology of the ear, but also the general principles and various details of aural surgery, have been described with as much accuracy as characterises other branches of surgery. In conclusion, Mr. Hodgson remarked that, although he had practised at Brighton for forty years, he had met nothing to support the theory advanced by some aural surgeons that exostoses of the meatus owe their origin to sea-bathing, although he had known prolonged "side-stroke" swimming in the sea cause severe ordinary otitis on the submerged side.

ANNUAL MUSEUM.

The exhibition of foods, drugs, and peptonised compound nutrients in the Museum of the British Medical Association at Brighton this year was of quite an exceptional character, and attracted a great deal of attention both from the members and the public generally. Most of the leading houses were represented, and an effort had evidently been made to ensure a display of new remedial agents.

Messrs. Allen and Hanbury showed not only drugs, but apparatus and accessories adapted for medical and surgical purposes. Their douches and sprays for the throat, nose, and ear were of especial interest, and were carefully examined by many of the visitors. Their cresolene has now been for some time in the hands of the profession, and the general opinion seemed to be in every way favourable to its employment. Their perfected cod-liver oil and tasteless castor oil are already established favourites, and call for no detailed criticism.

Messrs. Savory and Moore exhibited pancreatic emulsion, datura tatula specimens, and a fine collection of lamels and discs of all kinds. Their "fruit confection" and taurocholate of sodium pills coated with keratin are especially deserving of mention. The solid liniments of belladonna, aconite, camphor, and croton oil are a decided advance in pharmacy, and deserve to be better known.

Messrs. T. and H. Smith exhibited morphine, codeine, cryptopia, meconisine, gallic acid, tannic acid, jalap resin, scammony resin, and many alkaloids and active principles, for the careful preparation of which they have been so long renowned.

Messrs. Corbyn, Stacey, and Co. were represented by various drugs, chemicals, and pharmaceutical products of recent introduction. Their "Notes on Drugs and Chemicals" served admirably to explain and elucidate the various points of interest in connexion with their exhibit. Their new soluble cerium salts are a decided novelty, and will probably in time supersede the old-fashioned oxalate. Their liquor tolutanus is very valuable as a flavouring agent, and has many advantages over the syrup of the Pharmacopœia. Their apiol perles are useful, and will be found of service in the treatment of amenorrhœa and other allied conditions. In connexion with Messrs. Corbyn, Stacey, and Co.'s exhibition we may call attention once more to Valentine's meat juice, for which they are the agents. In this admirable preparation not only is the flavour of the meat preserved, but the albumen of the juice is retained in perfect solution.

Mr. Martindale exhibited his well-known Antidote Bag furnished with a complete supply of physiological and chemical antidotes, hypodermic syringes, and case of solutions. His capsules of glass encased in silk and cotton-wool, and containing bromide of ethyl, chloroform, iodide of ethyl, and nitrite of amyl, are admirable contrivances; whilst his granular effervescent preparations of caffeine hydrobromate, sulphate of sodium, and sodio-magnesian aperient are, beyond praise. The various odourless substitutes for iodoform—iodol, iodosalicylic acid, and diiodosalicylic acid—attracted much attention. We noticed a very fine specimen of mercurous tannate, the new remedy for syphilis, introduced by Lustgarten of Vienna. It is best given in the form of pills, each containing one and a half grains.

Messrs. Burroughs, Wellcome, and Co. showed some excellent specimens of Strophanthus hispidus, the new heart remedy and substitute for digitalis, introduced by Professor T. R. Fraser of Edinburgh. Their tincture of strophanthus is a reliable preparation, and is now largely employed. The Burroughs pure terebene, for the treatment of chronic bronchitis, winter cough, flatulence, acidity, and allied conditions, is free from all objectionable odour and taste, and may be prescribed with confidence. The new tabloids of antipyrin and trinitrin—the latter for the treatment of angina pectoris and asthma—are decided novelties, and deserve a trial. Their medical pocket cases, hypodermic cases, and medicine chests are excellent, and will be found most useful in country practice. This firm, we notice, makes a special feature of Dr. Liebreich's lanoline in all its various forms for external application.

Messrs. Thos. Christy and Co. showed an admirable collection of new and rare drugs, including acalypha indica, alveolos milk, kola nut, papaw juice, viburnin, and aletrin. The Siegesbeckia orientalis is said to be a valuable depurative, and to possess great healing properties when employed in the treatment of gangrenous ulcers and sores. The sentellarin prepared by the well-known firm of Lloyd Bros. of Cincinnati, for which Messrs. Christy and Co. are the agents, is a tonic stimulant to the nervous system, and is useful in low fevers and when the system is suffering from exhaustion due to over-excitement. Many of these remedies are as yet but little known, at all events in this country, but they have undoubtedly a great future before them. In connexion with Mr. Thos. Christy's admirable exhibit it is only fair to award a passing word of praise to the periodical entitled "New Commercial Plants and Drugs," so admirably edited by that gentleman.

Messrs. John Bell and Co.'s exhibit consisted chiefly of a collection of specimens of absorbent wool, with boric, carbolic, and salicylic acids, iodine, iodoform, perchloride of iron, and matico, all of which are of much value.

Messrs. Burgoyne, Burbidges, and Co. exhibited for Messrs. Parke, Davis, and Co. specimens of the well-known fluid extract of cascara sagrada and cascara sagrada, both of which are now so largely used in the treatment of obstinate constipation. The Semple's atomising inhaler shown by the same firm is an admirable contrivance, and commends itself to our notice in the treatment of hay fever and coryza. It may be employed for atomising almost any medicated fluid, but compound tincture of benzoin and a mixture of pure terebene and oil of cubebs are most commonly employed. We have no doubt that the employment of atomised fluids for bronchial affections will soon become more generally known.

Messrs. Fo[illegible] and Foster, of New York, exhibited [illegible] the most potent form of the fibrin-[illegible] increas. It is said to be

a powerful solvent of diphtheritic membrane, and to be capable of effecting a cure in well-nigh hopeless cases. The pepsine in scales prepared by this firm is a good digestive agent; whilst their zymine (extractum pancreatis) and zymine tabloids will always take a high place as therapeutic agents.

The Maltine Manufacturing Company showed, in addition to their maltine, specimens of Carnrick's beef peptonoids, Carnrick's peptonised cod-liver oil and milk, and Carnrick's soluble food for infants, invalids, and the aged—the last-named being described as a substitute for mother's milk. Peptonised foods of all kinds are now largely employed in the treatment of many diseases, and are of much value.

The Kepler Malt Extract Company have three new preparations—(1) malt and cream, consisting of two parts of the former and one of the latter evaporated *in vacuo* to dryness; (2) malt and milk food for infants and invalids, designed to correspond when diluted to human milk, the milk being peptonised; and (3) a malt, milk, and chocolate combination, made in the same way as the preceding preparation with the addition of a small proportion of pure coca. These new preparations are all of much value. The Kepler Extract of Malt Company also demonstrate by a series of microscopical specimens that their extract of malt and cod-liver oil is a true solution and not merely an emulsion—a point which may now be said to be fairly established.

In connexion with therapeutical appliances we must award a word of praise to Mr. Coxeter's batteries. His constant currents are remarkable alike for their cheapness and excellence. Some of the small batteries are admirably adapted for use by patients themselves, whilst others are most elaborately fitted, and will be found useful in the consulting-room.

In Section B, which included new books, surgical instruments and appliances, there were numerous interesting exhibits.

Messrs. Down Brothers showed many instruments which have been invented by Guy's Hospital surgeons, such as Golding Bird's trachea dilator, Lucas's forceps for removal of foreign bodies from the air-passages, Symond's œsophageal tube, nephrectomy instruments, lithotomy and lithotrity instruments, and midwifery instruments.

Messrs. Mayer and Meltzer exhibited a new spirometer by Dr. Mackenzie; a new intraocular syringe by Dr. M'Keown; and their patent self-adjusting piston.

Messrs. Weiss and Son had a collection of modern surgical instruments.

Mr. Hawksley showed a large series, including a very interesting set of appliances or aids for the improvement of hearing, as well as instruments employed in aural surgery.

Messrs. Coxeter and Son exhibited their new student's ophthalmoscope and a number of electric batteries and appliances.

Messrs. Evans and Wormull showed improved instruments for registering temperature, for aspiration and exploration, and improved appliances for dressing wounds. Exhibits were also shown by *Messrs. Krohne and Sesemann* and *Messrs. Arnold and Sons.*

Electric apparatus was exhibited by the *Electric Apparatus Company;* optical instruments by *Messrs. Pickard and Curry, T. Rowley and Son,* and *W. S. Stanley.*

Mr. H. K. Lewis and *Messrs. Cassell* showed a large collection of their respective publications; whilst charts, diagrams, &c., were exhibited by *Messrs. Danielssen and Co.* and *H. Silverlock.* Haviland's health guide map for Brighton was also appropriately exhibited.

In Section C, devoted to anatomical and pathological specimens, the most striking exhibits were the photomicrographs and microscopical preparations of Dr. Heneage Gibbes. *Messrs. R.* and *J. Beck, Medland,* and *E. Hinton* showed microscopes and microscopical appliances. Pathological specimens from the museum of the Sussex County Hospital were exhibited by Mr. L. P. Blaker; and specimens of cardiac thrombosis and others from the Great Ormond-street Hospital for Sick Children were exhibited by Dr. Chaffey. There was also a collection of specimens from the Alexandra Hospital for Children, Brighton. Dr. Tyson and Dr. Bowles of Folkestone showed several specimens; and Dr. Goodhart had sent some from Guy's Hospital museum. Dr. Beaven Rake exhibited some specimens of leprosy; and models and drawings of cutaneous disease were shown by Dr. Brooke, Dr. H. Radcliffe Crocker, and Mr. J. [illegible].

Besides drugs, Sections A [illegible] hygienic and sanitary appliances—[illegible] March the stall of Jaeger's woollen clothing and bedding; *W. Barlow's* "hygienic boots"; invalid couches, &c., by *J. Carter, Hamilton and Co., W. Watson, Leveson and Son.* Earth-closets were shown by the *Moule Sanitary Company,* and other improved closets and lavatory arrangements by the *Hygienic and Sanitary Engineering Company.* In the Pavilion Grounds *Messrs. Pugaard and Galschiot* showed a portable hospital on Tokeer's system.

BACTERIOLOGICAL MUSEUM.

This was perhaps the most unique of the week's exhibits, and too much praise cannot be awarded to Mr. E. Crookshank, who supervised and arranged it, and who attended during the whole of each day of the meeting to explain and demonstrate the apparatus and preparations. Three large rooms in the School of Science and Art were devoted to this purpose. In one there was a complete collection of bacteriological apparatus exhibited by F. E. Becker and Co., J. J. Griffin and Son, and R. and J. Beck, and by Mr. Crookshank. In another room there were to be seen all the processes which go on in the bacteriologist's laboratory—viz., cultivation of micro-organisms, of various kinds, in different media. These were exhibited by Mr. Crookshank and Dr. Penrose. The third room was devoted to an equally extensive display of microscopical preparations of bacteria and other pathogenic organisms, and also of photomicrographs and apparatus connected with photomicrography, all these exhibits being by Mr. Crookshank. On no occasion has there ever been collected so large a number of specimens and *matériel,* and to the great majority of those who visited the collection it must have been the means of opening up a new world. They were enabled to realise the remarkable extent to which the study of bacteriology has been carried, as well as to admire the industry and painstaking which had enabled so striking a demonstration to be made.

In closing this brief notice of the annual meeting of the Association, it is right to add that everything appears to have passed off with success, both the social and scientific elements being carried out with a spirit which could hardly be surpassed. Something, no doubt, must be put down to the fortunate circumstance of the place of meeting. Brighton looked at its best, and the extensive and admirable accommodation afforded by its excellent hotels was much appreciated by the members of the medical profession who came from all parts of the kingdom to take a part in this annual gathering.

The social entertainments of the week were brilliantly closed by the reception given by the Mayor and Mayoress at the Royal Pavilion on Friday evening.

Saturday was devoted to excursions, of which five had been planned—viz., one to the Isle of Wight by special steamer, the passengers landing at Ryde, where they were entertained at luncheon before returning to Brighton by the route they came; another to Arundel and Chichester, visiting the castle and cathedral at Arundel and being entertained at luncheon by the Duke of Norfolk, thence to Chichester, where a visit was paid to the cathedral and the party were entertained at tea by Dr. Tyacke and the medical men of Chichester in the old Council Chamber. A third party proceeded to Eastbourne, where they were entertained at luncheon, followed by visits to Romsey and Beachy Head; a fourth excursion was to Tunbridge Wells, with drives to Penshurst, Eridge, and Bayham; and a fifth to Hastings, when the new hospital with circular wards was inspected, thence to Battle and Normanhurst, the seat of Lord and Lady Brassey.

Amongst the special visits of interest made during the week there were two of notable prominence as indicative of the measures taken by the Brighton authorities to ensure a good water-supply to the town and an efficient system of drainage. On Wednesday a large party inspected the Goldstone Waterworks, and on Friday there was a similar inspection of the intercepting sewer about four miles to the east of Brighton.

DARENTH CAMP.—On Monday last the Right Hon. C. T. Ritchie, President of the Local Government Board, visited the camp of Darenth and inspected the site for the proposed permanent small-pox hospital. He also made a careful inspection of the temporary buildings now standing, which were in use during the last small-pox epidemic.

THE LANCET.

LONDON: SATURDAY, AUGUST 21, 1886.

THE annual meetings of the British Medical Association become year by year more interesting, and, we are glad to observe, more practically useful and scientifically important. Time was when these gatherings were less popular, for the affairs of the Association were in the hands of the few; but with the growth of the body itself there has been infused into its management a more enlightened spirit, and the work the Association performs is proportionately extended. With the striking success of the Brighton meeting—one of the most successful that the Association has known—and the harmony that marked its proceedings, still fresh in the mind, it may seem ungracious to hint at certain improvements which are yet needed at these gatherings if they are to fulfil their whole purpose. At the same time, the Council may not take it amiss if we present to their notice some matters which require attention and reform. The Association is now so large a body that its interests and affairs have increased enormously, and although it confides all its important functions to a representative Council and to numerous committees, the conduct of its business requires more organisation than at present obtains. It must have struck many that the time allowed for such business is lamentably insufficient. The practice of having addresses in medicine, surgery, and cognate sciences in addition to a presidential address is not one which we should care to see abandoned; but it must be confessed that the transaction of business after a lengthy address is unsatisfactory. Those who are attracted to the general meetings to hear the addresses are not disposed to linger whilst the real affairs of the Association are being discussed and arranged. The general meetings therefore are attended by a small number only, and no topics are adequately debated. The remedy will lie in an extension of the time allotted to the whole meeting, and the setting apart of at least one day for the sole purpose of such debate. It may be said that it is impossible to afford sufficient time to ensure anything like an adequate discussion of such topics; that the general body of members would take no share in such debates, which could end in no practical result. This may be so; but in an Association that undertakes many and varied duties the opportunity at least should be afforded for free discussion upon certain questions of interest; especially should such provision be made in the case of the reports of committees. The merely formal adoption of these reports, although doubtless showing the confidence the members generally have in the committees, is, after all, but a poor compliment to their labours Take, for instance, the subject of Collective Investigation, a work upon which the Association has expended much funds, with, as many think, but inadequate return. The Committee itself would have liked to hear openly any objections to its line of action that might be entertained, and any suggestions for the better conduct of an undertaking that, *per se*, is desirable and valuable. It appears that the Council have undertaken to inquire into the work of this Committee, which we should regret to see abandoned, but which ought, if possible, to be made to excite greater interest among the profession Nor can we leave this subject without alluding to the labours of the Medical Reform Committee, and the well-merited recognition accorded to its indefatigable chairman by the Association. It was a graceful as well as a just act to bestow on Dr. WATERS the highest honour it was in the power of the Association to confer. Turning now from the general business of the Association to the actual scientific work of the annual meetings, it is plain that there is room for improvement here also. Of late years the practice has grown up of having set debates in most of the sections. The practice was never more fully developed than at this Brighton meeting. Some of these debates were of considerable interest and importance, and were shared in by many well entitled to speak on the topics raised. Others, equally interesting and important, languished from lack of debaters, and took place before a scanty assemblage of members. It is worth considering whether it is advisable to encourage the reading of papers on subjects other than those set down for special debate, and also whether the number of sections should not be restricted, or some arrangement made whereby the sittings may be held at different hours.

In passing in review the proceedings of the week, the President's address naturally claims the first consideration. Although dealing with a somewhat trite topic, it was yet one which we do not think has ever yet been attempted in these presidential orations. As medical men and physiologists, it is not possible to gainsay the truth of Dr. WITHERS MOORE'S statements upon the physical injury induced by a too keen and undiscriminating course of intellectual training. The mind can only be forced at the expense of the body, and this is true of both sexes. Dr. WITHERS MOORE, however, intended his strictures to apply to the female sex, and prophesied dark things of the deterioration of the race if the present striving for equality in the higher pursuits continues to be carried on by those upon whom devolves, or should devolve, the cares of maternity and the training of the young. Brighton is an intellectual centre, and has long enjoyed celebrity as a training-ground for young women; but even there it is surprising what differences have shown themselves in the methods of training within a generation. What we must all declaim against is intemperance in study, without due regard to the maintenance of physical health. Only those who are really the "fittest," in body as in mind, should be permitted to enter for those competitions—which are, we fear, doing as much harm as good—that now universally prevail. The examination system needs to be far more jealously guarded than at present; and those who have the charge of the young should aim less at heading the list with their scholars, and more after the individual capacities and the physical well-being of those committed to their care. It is too late in the day—nay, it would be unjust and wrong—to exclude women from such avenues of employment that many of them are driven by necessity to seek; but we can exercise more supervision over their training, and do much to render their path easier and the race healthier by so doing. We must face the fact that there is a "redundancy" of [illegible] Mr. W. R. GREG phrased it; and

surely if there be any manhood or chivalry left (and we cannot share Dr. MOORE'S fears that women themselves will be responsible for the loss of this attribute), we ought to take care that the weaker sex have a fair field for the exercise of their faculties, not so much in the way of competition with men as in co-operation for the general good. This, however, is a large question, and one which has received a great deal of attention. Dr. WITHERS MOORE'S address has given rise to criticism of all kinds and from all quarters. He spoke with authority, and he kept within the limits of physiological knowledge; but we take it that he would be the last to advocate a return to the primitive conditions of life or to close the door of knowledge upon one-half of humanity. The other addresses at Brighton were of a high stamp. No better substitute for the lamented AUSTIN FLINT could have been found than Dr. BILLINGS, whose quiet humour, indicated by tone and gesture as much as by language, made the task of listening to a somewhat dry topic a rare intellectual treat. Mr. HUMPHRY and Dr. MAPOTHER placed clearly before their respective audiences the position of surgery and public health at the present day.

On certain features of the Medicine and Surgery Sections we have commented elsewhere. In the Pathology Section three interesting debates, unfortunately very thinly attended, were opened by Dr. Ross on peripheral neuritis, by Mr. HOLMES on aneurysm, and by Drs. STURGES and DOUGLAS POWELL upon pneumonia. The Public Medicine Section was amongst the most active, and here also an important practical subject—viz., the duration of infectiveness—was discussed preliminary to a collective inquiry. But we cannot undertake to enumerate even a small portion of the work done in the nine hours or so during which the several sections sat. Not the least valuable contributions made therein were the addresses of the sectional presidents, as might be expected when these include such well-known names as those of ERICHSEN, BROADBENT, CLOUSTON, DRESCHFELD, and LAUDER BRUNTON. Nor should mention be omitted of what was perhaps the most notable feature of the scientific side of this meeting—we mean the bacteriological demonstrations and museum, which were under the direction of Mr. CROOKSHANK. Some of those present may have recalled the fact that only five years ago, at the Worcester meeting, a very limited bacteriological demonstration took place in the Pathology Section. The newly-discovered tubercle bacillus and the mode of its demonstration then formed the staple topic. The contrast between that occasion and the present was striking, and spoke eloquently in evidence of the remarkable advance made in bacteriology, which may now well claim to be a special department of science by itself. Whether the next five years will show as great advances who can say? Perhaps with increased knowledge we may learn to modify our views as to the relation of bacteria to mankind, but it is hardly likely that we shall ever cease to recognise their importance.

The Brighton meeting was further notable for the visit of the delegates from the American Medical Association, headed by Dr. DAVIS, of Chicago, who had come to offer a cordial invitation to the Washington International Congress, over which Dr. DAVIS will preside [illegible] March the steps recorded to these gentlemen is, we may trust, of good augury for the success of the Congress, which at one time seemed likely to be in jeopardy. Again, this meeting was important in being the first since the passing of the Medical Act, and the decision of the Association not to interfere in the election of direct representatives to the Medical Council is a wise and salutary one. Lastly, from a social point of view, there seems to be no two opinions as to the character of the receptions and entertainments with which Brighton honoured her guests, whilst the suitability of this favourite health-resort for such a gathering was warmly acknowledged by all.

THE members of the British Medical Association assembled at Brighton have been favoured this year with two very interesting but very different addresses in Surgery. Both were retrospective, both dealt with the great advances which have been made in recent years in scientific as well as operative surgery, and the authors are both men of mark and long and varied experience. Mr. F. A. HUMPHRY reviewed the past, not so much with a view to point out rapid strides that have been made, though fully recognising and valuing them, but for the purpose of inquiring whether old theories, old opinions, old treatment, old books, are sufficiently studied and considered—in fact, to inquire whether we are not possibly going ahead a little too fast. Is the "medical side of surgery" sufficiently considered, and making equally rapid advances with the more purely surgical aspect of the science?

"Of late years," asked Mr. HUMPHRY, "how much has surgery done for medicine? Has medicine done as much for surgery, and has the medical treatment of surgical disease received the same consideration or made the same rapid strides as the study and development of operative procedure?" LAWRENCE, in an Introductory Lecture fifty years ago, boasted that modern surgery had greatly diminished the number of surgical operations, but both Mr. HUMPHRY and Mr. ERICHSEN now point out that the modern surgery of to-day has vastly increased not the number only, but the scope and magnitude of operations. Mr. HUMPHRY, however, reminds us that "an operation is an admission that medical treatment has failed in curing the disease." Up to a certain point Mr. HUMPHRY is quite right, and we heartily concur in this view; but we would ask whether it is absolutely true that there are more operations than formerly—that is to say, are there now performed more or fewer of the operations to which LAWRENCE referred: more amputations, for instance, *pro ratâ* than formerly? Of the new operations it is not fair to speak. Ovariotomy was unknown, and, with many other new operations, must be left out of count, though no one will argue that a successful ovariotomy is not an unmixed triumph, notwithstanding that medical treatment has failed. And herein lies, as it appears to us, the characteristic of modern surgery as understood to-day an increase in scope rather than in number or method of operations. Amputations remain much as they were, and the removal of tumours also has undergone little or no change. It is rather in the after-treatment that modern surgery comes in with its beneficent discoveries, and prevents patients from poisoning themselves and their neighbours with the foul discharges that were once con-

sidered part and parcel of the operation. It is this same knowledge of septic inflammation, its causes, its consequences, and the means of preventing them, that has enabled surgeons so largely to widen the range and scope of surgical proceedings. Amputations after compound fracture are fewer in proportion to the total cases than at any previous time, and this is entirely because the sources of danger are better understood than formerly. In such cases as these surely there can be no question of medical treatment, nor can there be any reproach in adopting surgical remedies in preference to therapeutic ones. Would it not be equally just to say that the fact of therapeutic measures being necessary is an admission that common sense has failed to arrest the disease, or has failed to keep clear of an accident? It thus appears to us that whether we adopt medicine or surgery depends on the nature of the case. It would seem that "medical surgery" is chiefly indicated in disordered function, and that surgery proper is the remedy for diseased or injured tissue. The one has to be set right, the other has to be removed: precious time is only too often wasted in trying therapeutic measures, when radical surgery can alone be of any avail.

Mr. ERICHSEN arrives at the conclusion that we have reached finality in the mechanical art of surgery both as to the expansion of its limits and the precision of its practice, and points out that further advances are to be sought not on the old lines, but rather in applying to it lessons which can only be learnt in the pathological laboratory. With the last of these conclusions we fully agree, but we doubt very much whether the mechanical side has been as fully developed as it is capable of. Indeed if it were so, would not surgery have obtained finality? The lessons of the laboratory are not surgery—they are science, and can only be applied usefully to the cure of disease by the mechanical arts which really constitute surgery. When we look back even on the past year only, we must recognise that science is ahead of surgery in many respects, and that she has already pointed out directions in which surgeons may successfully labour, provided only they can bring the necessary mechanical skill to bear. It would indeed be discouraging if practical surgery were already approaching finality. We venture to hope the contrary, and even to think that there is room for a vast amount of improvement. It will indeed be strange if, with the increased number of hospitals all over the country, the improved education of students, the great mechanical skill which is now available for the manufacture of surgical appliances, we do not continue to see fresh mechanical developments in the manipulative part of surgery. We can hardly think that surgical instruments or surgical dressings have reached their highest development. In ovariotomy, for instance, it was believed for a time that the use of LISTER'S antiseptic method had reduced the mortality of the operation to the lowest possible point, until it was shown that greater experience and skill in mechanical details could achieve, even without Listerism, ever improving results.

We make these observations less because we differ from Mr. ERICHSEN than because we hold that it will never do to minimise the great importance of mechanical skill and mechanical detail in surgery. Surgery is essentially an art; modern investigations are beginning to introduce a strong element of science. But, notwithstanding, surgery proper is only the mechanical application of science to the cure and prevention of disease; and the mechanical art must always be largely fostered and developed by anyone who would desire to become a truly great surgeon. Nor can we quite bring ourselves to think that surgery has reached finality as regards its limits. There are still several regions of the body for which surgical help is often wanted, and which, we believe, will sooner or later come within the limits of legitimate surgery. Thus, the lungs have only recently come to be regarded as susceptible of benefit from surgical treatment, and very much yet remains to be done before surgeons will be able to boast of their results. It is known that animals have survived the removal of an entire lung, and it may one day come to be equally well known that the human subject is able to bear such an operation as well as the lower animals. The spleen too has been removed successfully, but splenic surgery is still in its infancy; so also is liver surgery, a subject touched upon, but not greatly elucidated, at Brighton last week. Thus, it cannot be denied that very much remains to be done, of work which is largely mechanical, before these organs can be placed on the same footing, when diseased, as the ovaries, or even the brain.

AMONGST the many features at the recent meeting of the British Medical Association, none were more interesting or commendable than the discussion on cases in which disease of the valves of the heart has been known to exist for upwards of five years without causing serious symptoms. The discussion was opened by Sir ANDREW CLARK, who never spoke to greater advantage. The difficulty of compactness, where the number of cases and the number of ideas to be dealt with were so great, will appear the more clearly the more it is considered, and when we remember the little leisure that Sir ANDREW can have for either making notes or summarising conclusions or impressions, we are disposed to highly commend his discourse at Brighton. The notes of cases of valvular disease on which the discourse was based extended over a period of fifteen years. The number of cases was no less than 684. These were without serious cardiac symptoms. It is interesting to notice for what purpose these patients found their way to Sir ANDREW CLARK. He gave the following particulars: 272 complained of indigestion, 57 of rheumatism, 22 of gout, 44 of nervous ailments, 17 of eczema, and 4 of phthisis. Other persons with cardiac murmurs suffer even more slightly than these, and so pass through years of life without having their heart murmurs detected; for which, as Dr. BRISTOWE seemed to think, there is something to be said. He said that many people were made miserable through the discovery by doctors of cardiac murmurs, of which they had no previous knowledge or symptoms, and he very shrewdly said that though he was disposed to think himself quite sound in a cardiac sense, he would be very sorry to invite the criticism of Sir ANDREW CLARK or Dr. GAIRDNER. Medical men have themselves to blame very largely for the exaggerated fears of heart disease entertained by many, and for an exaggerated objection to have their hearts examined. The stethoscope is a handy thing, and the detection of a murmur not a very difficult operation. Some physicians, more intent on making a show of their own art than a study of

the patient's welfare, have been ready to magnify their little and cheap discoveries. The late Dr. STOKES used to tell, with strong disapproval, of a physician who, on detecting a murmur in the heart of a distinguished and useful public man, said, "Sir, I hear your death knell." Such a prognosis fulfils itself—as it did quickly in this case, though previously the patient was apparently in good health,—and the man dies, not of the cardiac disease, but of the nervous shock, literally of his physician. The great value of the discussion raised by Sir ANDREW CLARK, and most ably sustained by Dr. GAIRDNER, Dr. CLIFFORD ALLBUTT, Dr. BRISTOWE, and others, was not so much in any novelty of discovery announced, as in the evidence afforded by it of the wider and wiser view of disease taken by physicians and by all good practitioners, and of their perception of the fact that the run of people with heart disease do not fare very much worse than other people, if they only have the sense to consult sensible medical men and follow their advice. We heartily endorse Sir ANDREW CLARK'S teaching and that of the other distinguished authorities whom we have mentioned, and we bespeak for patients with heart disease, but with common sense and with due respect for medical teaching, more comfort from the profession than they have sometimes received. Let their common ailments be cured, let their diathesis be considered, let their intelligence be appealed to as to the best way of preserving their health and improving the muscular tissue of their heart as of their limbs, let Dr. ALLBUTT'S shrewd remarks as to the specially injurious effects of alcohol on the heart tissue, and Sir ANDREW'S exposure of the folly of over-eating and drinking, be duly pondered, and valvular disease will lose half its terrors. It is half—it is two-thirds—of the duty of a physician to find out the favourable facts about disease. He is not a mere pathologist, a mere hearer of murmurs. We cannot have absolutely healthy bodies; few of us have. Nearly all great works are done by those in whose health there is a flaw, to be detected, perhaps, but not to be magnified, "rather to be healed." As physicians cultivate this view of their calling men will flock to them for comfort and for guidance. Faulty men will not evade them, even if they happen to be physicians to life insurance offices, who have lessons to learn from the recent discussion at Brighton.

SOME two years ago Dr. VICTOR C. VAUGHAN, Professor of Physiological Chemistry to the University of Michigan, succeeded in isolating from some samples of cheese which had produced alarming symptoms in several persons a highly poisonous ptomaine, to which the name of tyrotoxicon was given. The effects of the poison were demonstrated on the investigator and several students, amongst whom dryness and constriction of the fauces, nausea, retching, vomiting, and purging were produced. Last November Dr. VAUGHAN succeeded in isolating the same poison from a sample of milk which had been tightly closed up for about six months, the appearance and effects of the poison being the same as in the previous experiments. Dr. VAUGHAN then placed samples of normal milk in his workroom, testing them from time to time. After about three months the poison was obtained from one of the bottles after certain processes, such as filtration, the rendering of the filtrate alkaline, and agitation with ether, the final outcome being that on evaporation the crystalline substance in question was left. A solution being made of the substance, ten drops were placed in the mouth of a dog three weeks old, and within a few minutes frothing at the mouth, retching, vomiting, muscular spasm of the abdominal walls, and subsequently watery stools were the result.

Following on this experience, Dr. VAUGHAN received a sample of melted ice-cream which had seriously affected eighteen persons who had partaken of it. The ice-cream had been flavoured with vanilla, and since those who had preferred lemon ice-cream had escaped any untoward results, it was at first assumed that the mischief was due to the vanilla. But experiments on individuals and otherwise showed that this was not the case. The cream substance itself being then tested in the same way as had formerly been done in the case of the tyrotoxicon, the aqueous solution, after spontaneous evaporation of the ether, was given to a cat two months old, with the result that in ten minutes retching, vomiting, and nearly all the symptoms already described supervened. The cat being subsequently killed, the stomach and small intestines were found to be full of a frothy serous fluid, but there was no local redness, and the organs examined appeared normal. A description of the symptoms which those who had consumed the ice-cream had suffered was later on received, and it is evident that they agreed closely with those observed in the cat, and that, in addition, occipital pain, excruciating back-ache, and in some cases stupefaction, dizziness, and numbness, were experienced. The throats of all were also œdematous, and the pulse varied from 90 to 120.

Dr. VAUGHAN holds that he had already shown that tyrotoxicon can be developed in normal milk in a period of three months, but that it now appears the development may take place much earlier; the production of the ptomaine being in all probability due, either directly or indirectly, to the growth of some micro-organism. As yet the poison has not been obtained in sufficient quantity to enable an ultimate analysis to be made of it; but it is asserted that it is, without doubt, a chemical body produced by fermentation. Further experiments, including the administration of the materials resulting from them to animals, go, however, to show that the production of the poison is in no way related to the ordinary decomposition of milk.

As regards the ice-cream in question, details are supplied as to its manufacture, and it appears that there was no difference in the preparation of the vanilla and the lemon ices except in the flavouring, both being made from a sample of milk obtained from the same cows, the milk from all the cows being mixed before the custard for both ices was made. But the lemon cream was frozen some time before the vanilla cream. A further experiment was next made with a small hardened lump of the substance sent for analysis. It had been left on the filter paper, and it was mixed with cream and eggs and made up into a custard in the same way as had been carried out with the original custard, and it was then placed in a refrigerator. A filtrate was subsequently prepared of a portion of it in a similar manner to that adopted in the original analysis, and the residue on the evaporation of the ether was dissolved in water and given to a kitten about two

months old, the result being the immediate production of symptoms resembling poisoning by tyrotoxicon. The experimenter himself partook of some, and was seized with nausea, vomiting, griping, &c. Reviewing his several experiments, Dr. VAUGHAN is of opinion that the fermentation going on in the custard, and probably begun in the milk, was arrested in that part flavoured with lemon by the freezing, which was begun immediately. But while the lemon cream was being frozen, that part of the custard which was to be made into vanilla cream continued to ferment, and before the freezing process was begun enough of the poison was generated to seriously affect those partaking of it.

This series of experiments is of importance in more than one sense, and one of these is referred to in some detail by Dr. VAUGHAN. He finds a great similarity between the symptoms of poisoning by tyrotoxicon and the symptoms produced in the human subject during certain diarrhœal epidemics. He especially refers to cholera infantum, and notes that this latter disease has a tendency to occur mainly at a time when decomposition of milk takes place most readily, and amongst persons whose surroundings are most favourable to fermentative changes, and he seems inclined to connect the infantile complaint with the production of tyrotoxicon generated from dried milk along the seam of a tin pail, or in a rubber nipple or tube, or in a nursing bottle. One thing is certain, that in this country cholera infantum, or fatal infantile diarrhœa, is due in many places to conditions quite apart from those of feeding; and whilst we would by no means exclude such a cause as Dr. VAUGHAN indicates from being at times one of those tending to the production of the disease he refers to, yet we should rather have looked for some such explanation as he offers in those groups of cases in which poisoning by articles of diet has occurred independently of infantile diarrhœa. The production of poisonous alkaloids, and their effects in causing sudden and serious symptoms in the human subject, is a matter calling for further study on both sides of the Atlantic.

THERE is no more interesting subject of study than that of the modes of causation of movements. Experimental investigation has given, and bids fair yet to give, results of no mean value. We have before us a paper entitled "Experiments on the Character of the Muscular Contractions which are evoked by Excitation of the various parts of the Motor Tract." It gives a succinct account of the researches carried out by Messrs. VICTOR HORSLEY and E. A. SCHAEFER at the Physiological Laboratory, University College, London.

The motor tract may be divided into four parts: (1) The cortical centres in the grey matter, the well-known motor region; (2) the fibres proceeding thence along the corona radiata; (3) the same paths in the spinal cord, together with the spinal motor centres in the anterior horns; and (4) the peripheral continuation in the anterior roots and efferent fibres to the muscles. The experimenters have found that all these portions are excitable by electricity; electrical excitation always evoking contractions of the skeletal muscles, provided only that the degree of anæsthesia be not too deep, or the nervous matter exhausted by repeated stimulation or other extraneous circumstances. In all the experiments the observers named have commenced by recording the contractions which result from excitation of the cerebral cortex, and the epileptoid contractions by which, in many cases, they are succeeded. The excitations were made at the rate of fifty, decreasing to forty, per second, and consisted of induction shocks obtained by varying the current of one or two Daniell elements sent through the primary coil of a Du Bois sliding inductorium; the variations were effected by the short-circuiting of the current by means of a vibrating metallic reed, which is kept in motion by an electro-magnet and the point of which dips in and out of a cup of mercury. After the tracings have been obtained from the cortex, this has been removed, and stimulation of the corona radiata practised. Then the spinal cord has been exposed and cut in the dorsal region, the excitations being repeated at the same rate upon the distal cut end. Finally, in a few instances the observations were completed by cutting and stimulating the peripheral end of the motor nerve.

FRANCK and PITRES and others have asserted that each excitation of the motor tract is translated by a single muscular contraction; so that twenty excitations per second would be recorded on the moving paper as twenty waves of muscular contraction. With above forty strokes per second a tetanic condition is produced in which it is impossible or very difficult to recognise the influence of the individual excitations. Messrs. HORSLEY and SCHAEFER have discovered that this rule does not hold good, at least as far as the first three divisions of the motor tract are concerned. The rhythm of muscular response to electrical excitation of the nerve centres is the same whether the electricity be applied to the grey matter of the cerebral cortex, or to the fibres thence proceeding, or to the spinal cord. The rate of the muscular rhythm is not the same as that of the excitation, except when the number of electrical excitations is less than eleven per second. It seems that some number of excitations above ten per second is required to make the rate of discharge from nerve centres as frequent as possible, and that, increase the rate of excitation as much as we may, we cannot get, so far as is known, by legitimate means, the motor centres to discharge their energy at any other rate than that of their own. This is indeed a most instructive law, and one which must open new ground, whilst enlarging our conceptions of the mode of action of the nervous system. It is further stated that the rhythm of muscular response in the case of voluntary contractions, and also of reflex ones, is essentially the same as that which results from the electrical excitation of the nerve centres. Again, it is asserted that the rate of muscular response in all cases of after-excitation (whether distinctly epileptoid in their nature or not) is fundamentally the same as that of voluntary and reflex contractions and of contractions immediately produced by a rapidly recurring electrical excitation, but the response in the case of epilepsy may present an apparent difference.

The principal conclusion to be drawn from these results, which have been supplemented by numerous observations on the voluntary and epileptoid contractions of man, seems to be best formulated thus: That every prolonged contraction of the skeletal muscles which is provoked by no matter what kind of excitation of any part of the nerve centres is a tetanic contraction which has been produced by

a series of impulses generated in the nerve centres, and passing along the motor nerves at an average rate of about ten per second.

If these observations be true—and there is every reason to be satisfied that they are,—we find ourselves in possession of information which is of the highest scientific importance. Certain questions remain to be answered. It is said that forty electrical excitations of the fibres of the corona radiata generally give only ten muscular twitches, fused into a tetanus, or we may safely say only ten motor nerve impulses. Whereabouts does this transformation of forty into ten take place? Obviously in the spinal motor centres. There must be in them a mechanism for the summation of nerve impulses, or else for the regulation in some other method of the numerous afferent impulses. The question whether the cortical motor centres have a rhythmical rate of discharge is not yet settled, though the fact that in some individuals the automatic action of the cortical centres (as the authors physiologically describe a voluntary contraction) may occasionally produce a muscular response of twelve or thirteen, or even more per second, whereas the automatic action of the nerve cells of the spinal cord appears to be never capable of originating a rhythm of greater frequency than ten per second, lends a probability to this hypothesis.

If the motor centres have a normal rate of discharge, is it too much to suppose that a similar law prevails for the sensory centres? Is not the sensation of tingling composed of vibrations having a regular rhythm?

THE summer is advancing, and as yet we are unvisited by the dreadful guest which threatened us. The cholera has been for some time unpleasantly near us—now in Spain, now in France, and now in Italy. No one can tell that even now it may not swoop upon us, as it has so often done before, without warning and without pre-recognised cause. With all our modern science the disease still remains mysterious, baffling dogmatic teaching and throwing us back incessantly upon the few certain facts we have gained. The hypothesis of zymotic origin and propagation has certainly been strengthened by scientific study, but it cannot even now be said to have arrived at the position of a theory, and its admission leaves much still to be accounted for. What we do know for certain is, that some kind of seed or virus is invariably, or, at any rate, commonly, present, and that this seed, or whatever we may please to call it, develops under certain conditions as yet imperfectly known, and does not develop under others. There seems no doubt that the disease may be spread by what looks like contagion, as in certain hospitals and ships, by the air, as in the memorable case of Southampton, reported on by the late Professor PARKES, and above all by water, in regard to which there are endless examples, beginning with the celebrated Golden-square case, and extending to the terrible epidemic in Spain last year. It is generally admitted that water is the most potent and perhaps the most frequent agent for the propagation of the disease, but it is certainly not the only one, for cholera spread through Southampton in spite of an excellent water-supply, and it has been known to commit havoc on board a ship supplied only with distilled water.

For the present public fear is at rest. We are well into August, and the cholera has not come. Every week brings us nearer to safety, and we, like the rest of the world, trust not a little to the chapter of accidents. Only one thing could rouse us, and that is a single case of undoubted cholera. Such an event, which might happen any day would at once cause a panic. It would then be discovered that all kinds of sanitary evils existed in our midst, that our river was a cesspool, our water-supply imperfect and most imperfectly guarded, and that our guardians were ignorant and inert, and deserved impeachment. A torrent of gross exaggeration would set in, and probably a measure of more or less frantic zeal would be passed in a hurry. All this has happened so often before, that its repetition in the next panic may be counted upon as a certainty. We always forget easily the lessons taught by calamities that have passed.

In contrast with this *laissez-faire* system, this contented waiting for the sharp lesson of experience so often taught before, it is our duty once more to urge the necessity of doing something before the danger arises. It is, we presume, useless to call attention again to the condition of the Thames and its tributaries, for each of them is undergoing a process of tinkering which will certainly be accepted as reformation unless some really great voice makes itself heard in Parliament and by the country. But it does not seem equally hopeless to beg that one simple matter may be attended to at once during the remaining short period of the year in which the danger is urgent. The intakes of our great Water Companies in London and many other towns ought to be guarded with the utmost vigilance. We will not at present discuss again the question whether these intakes are in themselves satisfactory. Let us assume that they are, that the Thames and Lea in London and the queer gathering grounds of Hastings are in ordinary times all that could be wished. The question still remains whether they are not liable through mere carelessness to a sudden pollution, compared with which the introduction of arsenic into a house-well would be a mere bagatelle. A few illustrations will serve to show the danger. The water of the Thames above Hampton is, let us say, perfect, but the river is a highway for trade and pleasure; many house-boats are moored nightly in it during the summer months, and a great number of barges—which are to all intents and purposes house-boats—pass up and down every day. We have no wish to figure as alarmists, but is it not obvious that any simple case of cholera—or even of choleraic diarrhœa, which seems to be sometimes almost as venomous as cholera—occurring on any one of these boats in the neighbourhood of the intakes may infect with a horrible poison a large portion of the water-supply of the metropolis? It is certain that no filtration after so recent an infection could render the water safe.

Those who wish for further information in regard to the spread of cholera by drinking-water should read the admirable article contributed to *Nature* on June 17th, 1886, by Mr. GEORGE HIGGIN. In that article the whole history of the cholera epidemic in Spain in 1884 and 1885 is given with remarkable lucidity, and its close connexion with water-supply is fully proved. The evidence is over-

whelming. Cities of bad sanitary repute but with good water-supplies escaped or were lightly touched, while others, such as Valencia, which were cleaner and better drained, but supplied with polluted water, suffered frightfully. So evident, indeed, was the connexion between infected water and cholera that in some towns—notably in Madrid, Toledo, and Seville—the doubtful sources were closed by public edict, and the pure supply was even patrolled day and night by armed guards to prevent the possibility of accidental pollution. These precautions seem to have been in every case successful.

Annotations.

"Ne quid nimis."

HEALTH OF ENGLISH WATERING-PLACES.

THE statistics bearing upon the recent health of English watering-places published in the Registrar-General's Quarterly Return, just issued, must afford considerable satisfaction to the thousands who are now migrating from our large towns to these holiday resorts. It appears that the mean annual death-rate during the three months ending June last among the more than a million of the resident population of forty-six seaside and inland watering-places of England and Wales did not exceed 15·6 per 1000. This rate was 2·4 below the general rate in the whole of England and Wales, and 1·9 below the mean rate among the nearly eleven millions of persons living in the rural districts, comprising the country parishes with their small towns and villages. With regard to the zymotic mortality in these watering-places, the report is scarcely less satisfactory. The annual death-rate from the principal zymotic diseases in these forty-six holiday resorts was 0·97, against 1·55, the mean rate in England and Wales, and 1·36 in England and Wales exclusive of the seventy-eight large towns. No zymotic diseases were registered during the quarter in Weston-super-Mare or in Tenby, while the rates in the other watering-places ranged upwards from 0·22 and 0·23 in Torquay and Whitby, to 2·11 in Eastbourne, 2·15 in Southend, 2·16 in Folkestone, and 2·63 in Herne Bay. In most cases in which the zymotic death-rate showed an excess this was due to the epidemic prevalence (during the three months ending June last) of measles or of whooping-cough. Measles was somewhat fatally prevalent in Hastings, Exmouth, and Blackpool; whooping-cough in Scarborough, Lowestoft, Folkestone, Eastbourne, and Worthing; scarlet fever caused 6 deaths in Yarmouth; and diphtheria mortality showed an excess in Southend, Folkestone, Rhyl, and Blackpool. It should also be stated that "fever," principally enteric, caused an exceptionally high death-rate in the watering-places on the Kentish coast, especially in the Isle of Thanet and in Dover. It should be borne in mind that the Registrar-General's figures afford no information of more recent date than the end of June, since which it is quite possible, for instance, that the outbreak of "fever" in the Isle of Thanet, which appears to have about equally affected the registration subdistricts of Margate and Ramsgate, has entirely disappeared. It would be judicious and useful to intending visitors if watering-places at this season of the year published monthly health bulletins readily accessible to the public. The health of English watering-places has now reached a general standard, and their reputation has most to gain from publicity and most to fear from false reports arising from the difficulty of getting promptly authentic information respecting their health and mortality statistics.

THE HAPPINESS OF "ANIMALS."

IT seems to us that a great fallacy underlies the interrogative proposition "Are animals happy?" and that the whole controversy arising out of the question raised by Mr. Cargill in the *Nineteenth Century*, together with any conclusions which have been arrived at, must be vitiated thereby. Practically the proposition amounts to this: man may be happy as an animal, and being thus happy, the question arises whether he is the happier or less happy because he has a bigger and better brain; or, to put the question in an inverted form, as Mr. Cargill would probably prefer to put it, "Are those animals which have less brain-power than man more or less happy than he?" The inquiry resolves itself into an endeavour to distinguish between the lower sensory and the higher cerebral forms of consciousness. If we were to cast this into a scientific form, it would be proximately, though not absolutely, accurate to say that one part of the experience of happiness depends on the activity of the cerebrum and the other on the functional energy of the sympathetic ganglia, and that the comparative prominence of these several sources of the experience of happiness is really what Mr. Cargill has been trying to determine. In like manner, one part of happiness depends on the absence of pain or irritation, and another on the sensation of what we call pleasure. In short, the search for any fixed point in the investigation pursued on the lines laid down by Mr. Cargill is fruitless. To speak frankly, the author does not possess that acquaintance with his subject which is indispensable to the prosecution of the inquiry he has instituted. Animals, including man, are happy—first in inverse proportion to their unhappiness by reason of a sense of suffering or the consciousness of need; and, secondly, in direct proportion to their capacities and opportunities for active pleasure. We have no means of knowing how much or how little of the so-called "happiness" of animals is negative or positive, or "physical" or "mental"—to use terms which are not definitive. The most we can do is to argue from the known to the unknown on the line of personal experience and assumed analogy. We can only judge of the consciousness of the speechless animals by their behaviour. It is possibly right to assume that, when a dog wags his tail and barks on being allowed to run loose, he is happy; but he also wags his tail and barks when he is eagerly awaiting the piece of meat which is being dangled before him. It may be the delight of anticipation which prompts him to express himself in this way, but there is no absolute proof that it is. Again, it is doubtless fair to assume that, if a bird chirps and hops about briskly, it is happy; but there is nothing to show that it is less happy when sitting quietly perched on a twig. We are only approximately right in inferring happiness from what is called "liveliness." Children are generally brisk when they are happy, but they are not always miserable when they are quiet. We fail to perceive the purpose of the investigation or to understand what is to be gained by it. Beyond question, very much of the happiness of mankind, and presumably also of the lower animals, is connected with the gratification of instinctive cravings and the avoidance of such suffering as results from unsatisfied needs. Hunger and thirst are distressing, and cause unhappiness; the appeasing of hunger and the assuaging of thirst give happiness because they put an end to unhappiness. Appetite and taste are diminutives of the sensation of hunger; and doubtless these are spread out and elaborated by development, so that degrees of appetite and specialties or refinements of taste minister to the sense of enjoyment [illegible] anticipation and in fact. In this way the highly developed, animal has

an advantage over the lower, or less developed, animal in the matter of powers and occasions of happiness; but collaterally, and in directly inverse ratio with the powers and capacities of being happy, are the powers and capacities of being unhappy. Whether the good outweighs the evil is a question, not of difference between "animals" and "man," but of fact, to be estimated, if at all, by experience and observation. If animals are happier, or less unhappy, than man, we should incline to think that the preponderance in their favour is mainly due to the immunity they enjoy from distrust of the future. He would be a bold man who should say that the human consciousness is presently the happier for its possession of powers and capacities of looking forward; but even in this respect the question is one of degree; for the dog that begs, and hopes, and licks his lips in anticipation of the morsel of food held before him probably enjoys a pleasure akin to that of the man who exults in the hope of future happiness. Meanwhile the dog runs merrily into the lethal chamber of death, and the sheep, unless he sees or smells blood, does not recoil from the slaughter-house; whereas man through fear of death is in bondage, and lives sadly for years because he must some day die. Doubtless this great drawback of our intellectual development, and what is called "enlightenment," is a fruit of our teaching and training; but that it is widespread throughout the human race cannot be questioned, and that it is a serious cause of unhappiness to the majority of men no one will venture to deny.

PROGRESSIVE PERNICIOUS ANÆMIA AND BOTHRIOCEPHALUS LATUS.

SINCE Biermer first described certain forms of anæmia which differed from those commonly observed in their progressive and serious character, the term "progressive pernicious anæmia" has found a place in our nosological nomenclature; but at first sight it seems strange that a disease which, in the form most commonly seen, is mild and easily amenable to treatment should now and again resist all our efforts, and slowly but surely tend to a fatal termination. Many authors doubt the existence of this particular malady, and the standard French authority, Jaccoud, regards it as possibly only an exceptionally grave form of the ordinary chlorosis or connected with a chlorotic cachexia. Any contribution which tends to increase our knowledge of the disease is much to be desired. An important step in this direction has been made in a paper in the June number of the *Deutsches Archiv für Klin. Med.*, in an interesting paper by Dr. Reyher of Dorpat, in which an obvious and tangible cause was found in thirteen cases presenting all the appearance of this disease. The etiological factor in these cases was bothriocephalus latus, which had taken up its abode in the alimentary canal, and which had obviously been the cause of the anæmia and accompanying state of disease, since on the removal of the worm the symptoms disappeared and health was quickly restored by the exhibition of simple remedies. Whether all cases of pernicious anæmia will in future be found to have a similar causation now that attention is directed to the point is doubtful; but the importance of the fact that cases appearing in all respects typical have been found to be due to the presence of internal parasites is great, and the medical man in presence of a diagnosis of pernicious progressive anæmia will do well to remember that such cases have been described, and he will take steps to ascertain whether in any given case such may not be the etiological factor, the discovery of which is so important both for prognosis and treatment. In most of the cases the presence of worms was unsuspected until attention was drawn to it by the appearance of fragments in the stools, or by questioning the patient as to whether such had at any time been seen. To give an idea of the cases we will briefly describe the author's first case:—The patient was a woman sixty-six years of age, who presented herself in a state of extreme debility and anæmia, which had continued for a year and a quarter and steadily gone on increasing during this time in spite of the fact that she had been under the treatment of several medical men. From the absence of evidence of internal disease, the duration of the symptoms, and the great severity of the anæmia and debility, the diagnosis of pernicious anæmia was made, and treatment was directed to a diarrhœa which was evidently exhausting the patient, but after a short period of time portions of a flatworm appeared in the stools, and with the exhibition of filix a complete bothriocephalus latus was expelled, head and all. From this date all the symptoms rapidly ameliorated, and in a few weeks complete health was restored, and the patient could go about her household duties. This mere sketch of a case will serve to indicate the lines on which the others run. In all, the anæmia and its accompanying symptoms disappeared after the expulsion of a bothriocephalus, and simple tonic treatment completed the cure.

THE WINDSOR TOWN IMPROVEMENT SCHEME.

AFTER four months' silence the possibility of improving the town of Windsor has again been discussed by the Town Council. The town clerk made a report, from which we gather that it will be necessary to acquire Parliamentary powers. After a very long discussion, it was decided that an expert should be consulted and requested to report as to the probable cost of obtaining an Act of Parliament granting compulsory powers to purchase: that is all. Even if the Act be ultimately obtained, we fail to detect in the scheme submitted any clause dealing with the gravest sanitary defects of the town. Windsor will be beautified, doubtless, its approaches rendered more worthy of a Royal borough which tourists from all parts of the world are in the habit of visiting; and there is to be a promenade along the banks of the Thames. The widening of the top of Bier-lane and the cutting through of Garden-court (a slum to the rear of Bier-lane) are the principal sanitary advantages. This will not suffice to redeem the reputation of Windsor. These are not the worst parts of the borough. It is far more urgent to do away with South-place, especially that side of the street where the houses have no back windows, no back yards, and no closets. One or two artisans' dwellings would take all the population now crowded in low and small cottages, such as those of the continuation of South-place, called Charles-place and Charles-street, where there have recently been cases of small-pox. These cottages take up much room just where there is no land to spare, and give very little accommodation. If Parliamentary powers must be obtained, a bold and thorough scheme should be put forward. By purchasing all the bad property the town could rebuild on the sites acquired houses that would let at such prices as to provide the means for an easy redemption of the debt. Windsor would thus possess in time a constant and rich source of income. Why look to rates, when rents are so much more profitable? The financial difficulties can be overcome more quickly by collecting rents instead of rates, and it would be easier for the town to keep its own property in sanitary order than to compel a number of small leaseholders and freeholders to see to the necessary repairs. Mr. Oberlin-Harris said, in the course of the discussion, that Windsor "meant to stand well in the eyes of the world, and prove that she really was a thoroughly healthy town. They knew that there was a tide in the affairs of men, and they knew, also, that there was a tide in

the affairs of the town, when they should take things and lift them up to a higher level." These are brave words, and should be taken to heart by every inhabitant of Windsor; and we would urge that it is high time such action should be taken as to no longer give any occasion of complaint or criticism. To the credit of the Town Council be it said, a vote of six to four was given in favour of consulting an expert on the improvement scheme. This is but a beginning, but still it is better than the "masterly inactivity" which has previously characterised that body.

MEDICAL WORKS AND THE LAW OF COPYRIGHT.

THE unfortunate state of international law as regards copyright is well illustrated by what has happened with regard to Dr. Dickinson's third volume on Renal Diseases, and which is most ably and kindly exposed by the Editor of the *American Medical Journal*. As issued by Longmans, this volume, which represents ten years of Dr. Dickinson's best work, contains 689 pages. It has been issued in New York as the August (1885) number of a "Library of Standard Medical Authors." In this mutilated form there are but 337 pages! This is significant enough, but the extent of the evisceration can only be understood by some instances given. Illustrations and cases are omitted wholesale, while it is coolly said that such omissions in no way interfere with the continuity of the work. In the chapter on Chyluria alone, thirteen and one-third consecutive pages of clinical report have been omitted, including two valuable tables. A case received into Guy's, in which two drachms of corrosive sublimate had been taken, is given without mentioning that the patient had suppression of urine or that he lived four days, and the facts of the post-mortem are omitted, of course without harm to the reader, who supposes he is getting Dr. Dickinson's careful work. We thank our American contemporary in the name of English journalists and publishers for the criticism. We sympathise deeply with Dr. Dickinson in seeing his great work thus misrepresented, and we feel sure that all visitors from the United States will join us in denouncing a system which is unjust equally to American readers and to honest and hard-working English authors.

LOSS OF WEIGHT IN EPILEPSY.

DR. F. HALLAGER, assistant-physician to the lunatic asylum at Viborg, has endeavoured to find an explanation of the diminution of the weight of the body after an epileptic attack. Kowalewsky was the first to draw attention to this fact. He states "that all persons suffering from any form of epilepsy lose in weight after each attack." "This occurrence is not equally great in every case, but depends on the duration of the disease and the intensity of the attack. The loss of weight is greatest after the first attack of a series of epileptic fits." Dr. Hallager has drawn up a table indicating the weight of the body and the quantity of urine and fæces excreted by the patients each day during his researches. Solid or liquid nourishment was given to the patients in proportion to the frequency and violence of the attacks. By a chart accompanying the paper in the *Nordisk. Med. Arkiv* it appears that whenever the curve of weight is considerably depressed after an attack there is also a corresponding elevation in the urine curve, of which no explanation is afforded by any increase of diet. When a loss of several pounds takes place, it is owing to the secretion of an abnormal quantity of urine. Dr. Hallager has been unable to determine whether the production of urea is also increased by the attack, but he believes the increased formation of urea is not sufficiently great to be of importance in the loss of weight. The diminution of weight caused by an epileptic attack he considers to be due to an increased secretion of urine after the fit. M. Kowalewsky insisted that psychic epilepsy, as well as the *grand* and *petit mal*, is followed by a diminution of weight. This is contrary to Dr. Hallager's opinion, who believes that there is no diminution during this psychic state except when the patient refuses all nourishment, and that the quantity of urine secreted is much less than normal. This is no doubt due to a reaction after the preceding augmentation. The fact that psychic troubles of an epileptic origin (especially when of long duration) may, like other maladies, cause a loss of weight is natural; but this loss which arises from general emaciation, has nothing in common with the diminution of weight after an epileptic attack, which results from a diminution of the quantity of water in the body, due to preceding augmentation of urine.

LONDON DUSTBINS.

DR. DANIELL, chairman of the Wharves and Plant Committee of the Kensington vestry, calls our attention to a paragraph in our last number on this subject, which appears to imply that the vestry still trust to contractors for the removal of house refuse. The difficulty the vestry have to overcome is not that of removal, which is in their own hands, but that of disposal of the refuse after its collection; and this difficulty, Dr. Daniell tells us, is hourly increasing. We trust the special committee recently appointed will see their way to recommending a method which will finally solve this problem, and set an example which other parishes may with benefit copy. Mr. J. W. Wood, of Liverpool, writing on the same subject, tells us that he has invented and patented a dustbin which can be used in houses, where the dust can be removed from a passage behind the house and emptied immediately into the dust-cart without incurring the risk of dropping the refuse or the necessity of temporarily depositing it on the ground. The apparatus will be exhibited in a few days at the Liverpool Exhibition, and from the description appears well calculated to answer its purpose.

THE INFLUENCE OF SMALL-POX HOSPITALS.

DR. TRIPE, in his last annual report to the Board of Works for the Hackney District, recurs to the subject of the diffusion of the small-pox infection around the Homerton Hospital. During 1883-84 there had, quite apart from the actual treatment of cases in the hospital, been a large traffic in small-pox patients to and from the hospital on their way to the hospital-ships, as many as 859 cases being thus removed in one single month. In the year now dealt with—namely, 1884-85—the largest number per month was 113, and it is believed that all these had received treatment in the hospital. With this diminution of cases the amount of spread around the hospital has also diminished; but still Dr. Tripe is able to show, by means of a map and of tables, that the rate of attack from small-pox is, as heretofore, more prevalent within the quarter- and half-mile radius around the hospital than elsewhere in his district; and he is further of opinion that the risk to a locality in which such a hospital is placed is not to be measured only by the number under treatment at any one time, but partly by the number moved to and from the hospital. Dr. Tripe also considers that the evidence adduced by Mr. Power as to the probability of the disease being spread through the air when only some nine or ten patients are under treatment is very strong, although it does not follow that similar results would ensue on every such limited aggregation. Here he is in entire accord with Mr. Power, who has all along indicated that other considerations, such as meteorological conditions, probably have a [illegible] the case. But as to the

reality of aerial infection Dr. Tripe has no doubt, and he takes the opportunity of stating his belief that the large ward system at present in use in the Asylums Board hospitals is more likely to be injurious than small wards containing only four or six patients. And if this be so—and we are entirely in accord with Dr. Tripe—what must be the effect of large aggregations of small-pox patients, such as are even now being contemplated? The fact is that we have come to a point in the history of small-pox in which it becomes important to learn whether some of our small-pox hospitals, and especially those within the metropolitan area, are not, as at present organised, tending rather to secure the maintenance of the infection in our midst than to get rid of it. Dr. Tripe very properly says that the whole question requires much more investigation. This investigation can only be properly made by the medical staff of the Local Government Board, and, looking to the responsibility of that Board as to the doings of the Metropolitan Asylums Board, it is certainly time that a complete and searching inquiry should be made into the behaviour of small-pox, as influenced by the hospitals maintained for the purposes of the metropolis.

THE NINTH INTERNATIONAL CONGRESS.

CIRCULAR No. 2 is issued by order of the Executive Committee. The Congress will meet in the city of Washington, the capital of the United States, on Monday, Sept. 5th, at noon. The patrons of the Conference will be the President of the United States (the Hon. Grover Cleveland), the Secretary of State (the Hon. Thos. F. Bayard), the Presidents, respectively, of the Senate of the United States, and the Speaker of the House of Representatives. The President of the Congress will be Dr. Nathan S. Davis, Professor of Medicine, Chicago. Our own British Schools will be well represented, if we may judge from the list of vice-presidents, which includes Dr. McCall Anderson of Glasgow, Professor Annandale of Edinburgh, Mr. Golding Bird of Guy's, Dr. Dolan of Halifax, Professor Fraser of Edinburgh, Sir William Mac Cormac, Sir Dyce Duckworth, Dr. Klein, Professor Macleod of Glasgow, Dr. Murrell, Mr. Richard Quain, Dr. J. Burdon Sanderson, and Mr. Simon. Other European countries will be duly represented in the vice-chairs. The Executive Committee invite all regular medical men to the Congress. Communications relating to appointments for papers should be addressed to Dr. John B. Hamilton, Secretary-General of the Congress, Washington, District of Columbia. All communications referring to the business of the Executive Committee should be addressed to Dr. Henry H. Smith, Chairman of the Executive Committee of the Ninth International Medical Congress, Philadelphia, Pennsylvania. There are several errors of name, title, and address in the circular, which should be corrected speedily.

BACTERIUM TERMO TREATMENT.

DR. ROQUER Y CASADESUS of Barcelona having a case of laryngeal and pulmonary phthisis of an advanced character, and wishing to test the value of Cantani's bacterio-therapeutics, asked Dr. Rodriguez Mendez, a well-known microbiologist, to assist him. The condition of the patient was carefully ascertained in consultation, cavities being found in both apices. There was a high temperature, also profuse sweats, diarrhœa, profuse expectoration, great dyspnœa—in fact every sign of acute pulmonary tuberculous degeneration. The patient was in the seventh month of pregnancy. A pure culture of bacterium termo was then prepared by Dr. Botey, and made use of by means of inhalations twice a day and by intra-laryngeal applications. After a few days the patient's condition [illegible] the temperature having fallen from [illegible] This improvement continued till labour came on, which was of a normal character, but shortly after delivery the woman's condition became alarming, and she died in twenty hours. Dr. Roquer concludes from this case that, whether the remission of temperature was or was not due to the treatment, the bacterium termo was perfectly innocuous, as Professor Cantani states it to be. Dr. Philipovich, who has made several trials of the treatment of phthisis by the inhalation of cultures of bacterium termo, has published a paper describing the results obtained in the reports of the Odessa Medical Society. In one case the inhalations had to be stopped in consequence of the condition of the patient becoming worse, three cases died, and two were discharged. Dr. Philipovich's observations agree in general with those of Dr. Görbersdorf, and are decidedly inconsistent with those of Professor Cantani. The expectoration did not diminish, but it was rather more easily secreted, and so the dyspnœa was less. This, however, was probably due to the action of the water and the better aeration of the lungs, rather than to the microbe. In one case the quantity of sputum was increased, and it became more liquid and very offensive. At the necropsy in this case cavities were found containing tolerably pure cultures of bacterium termo. In none of the cases did the tubercle bacilli in the sputum disappear or even diminish, though the inhalations were continued for seven weeks. Again, no effect was produced on the temperature or sweats, and in all the patients there was noted a greater or less loss of weight. The author concludes that no beneficial effect can be looked for from the use of this method of treatment; indeed it would rather appear, from the post-mortem appearances above mentioned, that inhalations of bacterium termo may be positively hurtful to the human organism.

MUZZLED OR LED.

A DOG in the streets must be either muzzled or led by some competent individual. There is no alternative. He is not under proper control if led by a little girl or boy, from whose feeble grasp or easily frightened hold the dog may readily escape. The object of the police regulations is to stamp out hydrophobia in man by the abolition of rabies in the dog. The police will not have a chance if the regulations are not strictly enforced. Lovers of the canine race must be called "hysterical," "overweeningly sensitive," &c., if they persist in arguing that the muzzle is a torture or the restraint of being led an inhumanity. The total number of dogs not under control taken by the police to the Dogs' Home during the month of July was 2898. Of this number 52 were killed in the streets as rabid, and one developed rabies at the Home. There were no less than 587 summonses taken out against owners of dogs not under control. We are glad to state that the majority of these resulted in convictions. Sixty-five persons are known to have been bitten during the month. One case of death from hydrophobia has been reported as having occurred in July in London.

PHYSIOLOGICAL ACTION OF LUNG TISSUE.

AT the twenty-sixth July meeting of the Paris Academy of Sciences, M. L. Garnier commented on the physiological action of pulmonary tissue in the exhalation of carbonic acid. He observed that it is difficult to explain by simple physical action the passage of carbonic acid from venous blood into the atmosphere of the pulmonary alveoli; that displacement would, however, be easily intelligible if chemical action intervened to set it in motion. M. Garnier's experiments appear to demonstrate the existence in the pulmonary tissue of an acid body, differing from taurine, capable of decomposing the carbonic combinations of venous blood and setting free carbonic acid gas.

SMALL-POX AND VACCINATION.

OUR attention has been called to a communication in the *New Zealand Times* of April 28th in connexion with this subject. It is possible that its author thought it would escape the notice of those who knew, and in any case have the desired effect on those who did not. The primary object was to sow the tares. The pertinacity with which statements are repeated that have been refuted over and over again shows the poverty of the material in the way of so-called facts which the imaginative but mischievous opponents of vaccination have to make use of. The way in which, too, these statements are made to do duty is amusing to those who know how such matters are worked. After a tour at home, followed by the inevitable contradiction, they reappear in the colonies. Now let us examine a few of the statements. It is not true that eighty-one cases of small-pox occurred among the revaccinated European army in Egypt in 1882, of which seven proved fatal. The number of cases recorded for that year was three, and no deaths. It has not been maintained, as asserted, that the army is a perfectly vaccinated class, but rather that if the provisions for vaccination and revaccination could be absolutely carried out it should be so. Mischievous and irresponsible "faddists" have no doubt done all they can to foster ignorant prejudices, but it is a ridiculous exaggeration to say that the operation of revaccination in the English army is regarded with unmitigated dread and disgust. Small-pox is a very common complaint among the native population, not only of Lower Egypt, but also all up the valley of the Nile, and our troops have been almost constantly exposed to its contagion. Revaccination has been attended with much difficulty in Egypt, for various reasons. Since the arrival of the British troops in that country in 1882 up to the end of 1885, with an average annual strength of between 11,000 and 12,000 men, there has been a total of thirteen deaths from that disease. The communication we are reviewing literally bristles with inaccuracies. Let us take two quite indiscriminately. There is no need to select. It is stated that some years ago thirty recruits from Stockport were vaccinated at Shorncliffe, of whom thirteen died of the operation. No information to that effect can be obtained from any official record or from any other source. A quotation is made with inverted commas from a particular page of the forty-fifth annual report of the Registrar-General. We turned to the page in question, but failed to find it there or anywhere else.

COCAINE POISONING.

DR. LUCAS CHAMPONNIÈRE'S *Journal de Médecine et de Chirurgie* for last month devotes an article to cases of poisoning by cocaine, based on researches of M. Chatellier. The employment of the valuable remedy is not contra-indicated by the occasional manifestation of toxic effects, nevertheless it is important to know them. In a case cited by Dr. Speer, a man was in the habit of self-injecting cocaine to combat the effects of drunkenness. The action closely resembled opium poisoning, but the patient recovered under appropriate treatment. A woman, aged twenty-five, to combat hay fever, had a watery solution containing fifteen centigrammes of hydrochlorate of cocaine injected into the nose. In about twenty minutes she became giddy, was oppressed by a sense of weakness, and could not see distinctly. A little later she was in a semi-comatose condition, pulse not countable, slight dyspnœa, pupils dilated. These symptoms disappeared in the course of three hours under the influence of internal stimulants and external friction. Dr. Ziem of Dantzic reports that he injected under the conjunctiva of a man, aged forty, two drops of a 40 per cent. solution. In the course of a few minutes the patient became pale, the forehead bedewed with sweat, and respiration embarrassed. He states that seventeen cases of cocaine poisoning have been reported by oculists. In three the agent was injected hypodermically; in fourteen merely into the conjunctival cul-de-sac. The usual symptoms are pallor and clamminess of the face, vertigo, and great prostration, sometimes lasting for days. Headache and vomiting are infrequent. In one case, after sub-conjunctival injection of fifteen drops of a 2 per cent. solution, the gait became uncertain, articulation indistinct, and memory lost. In another case sub-conjunctival injection of eight drops of a 3·5 per cent. solution produced loss of consciousness and convulsions. M. P. Tissier relates the case of a child, aged four, affected with whooping-cough and coryza, whose nasal fossæ were pencilled with a 1 in 30 solution of hydrochlorate of cocaine. In the afternoon the eyes became distorted and the child convulsed, but these symptoms disappeared without treatment.

MIDDLESEX HOSPITAL RESIDENTIAL COLLEGE.

WE have received a copy of the prospectus of a Company formed for the purpose of building a Residential College in connexion with the Medical School of the Middlesex Hospital. An opportune time appears to have been chosen for initiating such a scheme, as the desirability of affording some safeguards against the dangers which surround medical students, and of imparting something of the collegiate spirit to their life in London, is now attracting considerable attention. We are glad to observe that whilst the Earl of Latham and Major Ross, M.P., chairman of the Weekly Board of the hospital, are amongst the directors of the Company, the medical and surgical staff are also fully represented—an earliest, we take it, of that hearty co-operation of the lay and medical elements which has always been so pleasing a feature of the hospital. The college, which will accommodate thirty students, under the supervision of a resident warden, will overlook the hospital garden and will immediately adjoin the new school buildings which are about to be erected. Such a scheme cannot but commend itself to many parents of students, and should conduce to the best interests of the school. We heartily wish it success.

CHOLERA IN SOUTHERN EUROPE.

CHOLERA would appear to have acquired a firmer hold on Southern Italy than it had a few weeks ago, and fresh places on the Adriatic continue to be attacked, the last place being Biscaglia. The epidemic is still most severe at Barletta, but the daily number of deaths has been reduced from some 60 to 28. In all, 310 fatal attacks have taken place there during the week ending August 17th. It is evident that much of the news as to cholera in Southern Italy is not officially announced, and there is hence every reason for believing that the epidemic there is of greater severity than has as yet been apparent. In North-eastern Italy the disease is still maintained at most of the places last announced as being infected, and a few additional towns within the same area have been newly attacked since our last report. In some towns, notably in Venice, Verona, and Padua, the rate of mortality is still small as compared with the number of attacks. The most continuous records of maintained cholera reach us from Bol[illegible]a and Ravenna, where 41 and 60 deaths respectively occur[illegible] from Aug. 11th to Aug. 17th, and from Verona and Pad[illegible] In all, during the week under consideration, the fatal [illegible]cks of cholera in Italy have numbered 582, but it is [illegible]ll known that the disease is widely prevalent in many [illegible] the smaller townships in the province of Venice and e[illegible]where, as to which no records are as yet issued. In [illegible]les 9 deaths have occurred amongst immigrants from [illegible]cted localities. Cholera is still maintained at Trieste, whe[illegible]he deaths in the week ending

the 17th inst. have been 24; it is less prevalent in Fiume, but one or two fresh places in Istria have been attacked. In the Croatian villages, whence news comes most sparingly, the disease is somewhat widespread, and it was recently announced that up to Aug. 11th there had been 228 cases and 118 deaths in various portions of the province.

INFLUENZA IN HAVANA.

DR. JOSÉ R. MONTALVO gives an account in *La Enciclopedia*, a Cuban medical journal, of an epidemic of influenza (*gripe*) which occurred last year in the children's wards of the Havana Casa de Maternidad. When the temperature was high, and it sometimes rose to 41·5° and 42° C., he found frequent baths at 35° C. of the greatest value, especially, of course, in the cases where the pyrexia itself appeared to constitute the chief element of danger. These baths were given to children of ages varying from six months to three years, and were supplemented by internal treatment with digitalis, carbonate of ammonia, brandy, port wine, and, where necessary, by ipecacuanha emetics. Where there was diarrhœa the subnitrate of bismuth in quantities of from one to nearly four drachms per diem was given, West's plan of giving minute doses of castor oil and emollient enemata being substituted where there was inflammatory diarrhœa. Dr. Montalvo's paper would have been more valuable if he had given some statistics of the number of cases at different ages and the results. Still, as more than one author whose works he consulted had omitted all mention of the affection, his paper will be valuable in calling attention to it and its treatment on rational principles.

SURGERY AT BRIGHTON.

THE discussion on supra-pubic cystotomy occupied the Surgical Section during the whole of the afternoon of Wednesday, at the Brighton meeting of the British Medical Association last week. Sir Henry Thompson introduced the subject, which has been so recently discussed in London that novelty was hardly to be expected at Brighton. But, on the whole, the feeling of the meeting was evidently in favour of giving this operation a fair trial, not only in cases unfitted for any other form of lithotomy, but also in cases independently of their fitness or suitability for lithotomy or lithotrity. There can be no doubt that grave consequences—incontinence of urine and loss of sexual power—have sometimes followed apparently successful perineal lithotomies. Mr. Cadge was appealed to for information on these points; with a very large experience in lateral lithotomy, and in a provincial town, it was thought he might possess facilities for discovering in what proportion of cases such accidents had occurred. Then again, as a strong point in favour of the supra-pubic method, Mr. Cadge's experience of the frequency of recurrence after lithotrity was quoted. It was urged that the supra-pubic operation was quite easy of performance, and was one which did not need any large operative experience, and was therefore especially adapted for surgeons in the country. Several speakers, on the other hand, referred to the difficulty of the lateral operation in young children; moreover, lateral lithotomy was known to be followed in some few cases by sexual incompetence. It must be admitted that the advocates of the high operation have several important arguments in their favour, while the opponents have not a single strong point to urge against its adoption, even as a routine practice. The great divergence of opinion in regard to many technical details—such, for instance, as to the desirability or otherwise of suturing the bladder,—showed that surgeons need the knowledge which experience alone can bring. Meanwhile, we hope that all cases in which this operation is practised will be carefully recorded; for the merits of the operation cannot be adequately tested except on a clinical basis. On the Thursday, a discussion on the surgery of the liver was arranged for, but for some reason it fell flat, notwithstanding that several interesting papers were contributed. The general opinion arrived at appeared to be that patients were not much benefited by cholecystotomy. On the Friday, Mr. Horsley's paper on the most recent advances in the surgery of the central nervous system attracted a large and enthusiastic audience. Besides showing the possibility of accurately diagnosing the seat of disease and of successfully removing it, Mr. Horsley claimed these results as a direct outcome of experimental investigation on animals. In addition to the foregoing set subjects for discussion, a large variety of other surgical papers was contributed.

MICROSCOPICAL DIAGNOSIS OF A NEPHRO-INTESTINAL FISTULA.

NEPHRO-INTESTINAL FISTULÆ are certainly rare. Dr. R. Wernicke, who publishes his observations in the *Anales del Circulo Médico Argentino*, has only met with three cases in literature, and so believes his to be the fourth. In May last he was asked by Dr. Montes de Oca to examine a sample of urine in a flask. The colour was yellow and there was some turbidity, also a copious yellow sediment containing grey clots of irregular shape. The reaction was alkaline, and the liquid after filtration contained albumen. The turbidity was evidently due to putrefactive microbes and leucocytes. The sediment on microscopical examination showed the presence of leucocytes, red blood-corpuscles, vesical epithelium, caudate or pyriform epithelial cells from the pelvis of the kidney, granular casts, particles of fatty matter (highly refracting and of a yellow tint), quantities of small aggregations of granules (highly refracting, some of the granules being attached to one another, and some surrounded by a yellow, structureless envelope, being in fact coagulated milk); and lastly, a number of striated muscular fibres, stained with biliary pigment, the striæ being more or less obliterated, according to the stage of digestion which had been reached. As there was no question that the whole of the contents of the flask had been passed from the urethra of a man, there could be no doubt that a communication existed between the urinary and digestive passages. The cause of this ulceration was also diagnosed by further microscopical examination of the sediment, which revealed the existence of tubercle bacilli, which were so clearly recognised both by their form and their behaviour with reagents as to leave no doubt in Dr. Wernicke's mind of their precise nature. The case not being under his care, no clinical details are given. It is seldom, however, that the microscope alone enables so much of a diagnosis to be made in a rare and intricate case such as this.

PROSECUTIONS UNDER THE DENTISTS ACT.

WE are glad to see that the British Dental Association are steadily carrying on their prosecutions under the Dentists Act. In the present cases Herr Arnemann was summoned before the Nottingham magistrates last week that he did unlawfully take and use the name or title of dentist, implying that he was registered. For the defence it was urged that he had a diploma from the University of Berlin; but as this foreign qualification is not recognised, the magistrates convicted the defendant, and ordered him to come up for judgment when called upon, and added that in this event he would be severely punished. The other prosecution was of a similar nature. August Friederik, practising at Walthamstow, was summoned at Stratford on the 18th inst. for, not being registered under the Dentists Act, 1878, using the letters D.D.S. or some other title implying that he was

registered under the said Act, or that he was ... person specially qualified to practise dentistry. It was ... d on the defendant's behalf that he was a fully qualified an, that he held an American diploma in dental surgery, and that he was willing to go through any examination in that art. The magistrates imposed a fine of 20*s.* and costs.

THE BACILLUS OF MALARIA.

IN 1879 Professor Tommasi-Crudeli published, in the *Atti della Reale Accademia dei Lincei* at Rome, a memoir on the distribution of the subsoil water of the Roman Campagna, and on its influence in the production of malaria. In this research, which proved the starting-point of new studies on the etiology of malaria, the author traced the natural history of this morbigenous ferment, discarding many errors and prejudices of old medicine, and maintaining that the causal agent of the disease could only be a living organism. Towards the close of the same year Tommasi-Crudeli and Klebs published in the same *Atti* a memoir embodying the results of inquiries on malaric airs and soils, and of experiments on rabbits, proving that the living organism is a schizomycete, named by them "bacillus malariæ." As the result of researches on the individual affected with malaria, Marchiafava and Celli announced that within the red-blood globules are constantly found plasmatic bodies (*corpi plasmatici*) endowed with lively amœboid movements, in which the hæmoglobine is transformed into melanine (melanæmia); and in a further memoir which they have published this year, they suggest as a more probable hypothesis the opinion that those plasmatic bodies are the living organisms which produce malaria. Thus Marchiafava and Celli confirm in substance Tommasi-Crudeli's opinion, that a living organism is the cause of malaria, but they regard its form as differing from a schizomycete. These observations are embodied in a note with which Todaro prefaces a communication by Tommasi-Crudeli in the April number of the *Lincei*, on "a bacillus found in the malaric atmosphere around Pola (Istria)." This bacillus resembles the most typical forms of the bacillus malariæ which Tommasi-Crudeli and Klebs found in the air and subsoil of the Roman Campagna, which is *par excellence* the home of malaria. Since identity of form does not necessarily imply equality in infective power, Tommasi-Crudeli reserves his definite opinion on the bacilli discovered in the air of Pola, until they shall have been submitted to experimental research, a plan of which he has sketched.

CREMATING DUSTBINS.

IN a recent report to the Marylebone vestry Mr. Wynter Blyth directs attention to what he calls the "cremating dustbin" attached to the Queen Charlotte's Lying-in Hospital. It is simply a small crematorium, built in the shape of a dustbin, of fire-proof bricks, with an iron lid, proper doors and gratings, and a long chimney-shaft carried up to and beyond the roof of the building. This dustbin is charged with combustible material and the various offensive matters which are necessary refuse of every hospital, and they are from time to time consumed. The heat is intense, there is no nuisance, and experience has shown that ordinary house refuse contains so large a quantity of carbon that no additional fuel is required. It is suggested, further, that it would be to the advantage of all hospitals, hotels, large boarding-houses, schools, and other institutions if each were provided with one of these cremating dustbins. In an ordinary household all vegetable refuse and offensive matter should be destroyed in the kitchen range; and to avoid nuisance it is an excellent plan to throw all vegetable refuse into the cinder-tray beneath the fire, where it gets dried up and partly charred, before finally putting it into the fireplace itself.

SUBLIMATE INJECTIONS IN GONORRHŒAL CYSTITIS.

THE history of an obstinate case of gleet and cystitis is given in *El Dictamen* by Señor García Andradas, which after being treated unsuccessfully by means of injections of nitrate of silver, yielded very quickly to injections of corrosive sublimate. The patient, who was a river fisherman, contracted gonorrhœa, which was treated for a month with balsams and astringent injections. The discharge then became serous, and exquisitely painful vesical tenesmus supervened, the calls to urinate being so frequent as to give the man no rest. An attempt to pass an instrument occasioned the greatest agony when it came in contact with the prostatic portion of the urethra. The diagnosis made was that of acute prostato-cystitis consequent on gonorrhœa, and so the local application of a sublimate solution appeared to be the most rational treatment, as it had in the author's hands proved very beneficial in cases of subacute cystitis due to the same cause; but it was thought well to try first Guyon's treatment. With great difficulty, owing to the extreme sensitiveness of the urethra, an elastic catheter was passed to the prostatic portion, and ten grammes of a 1 per cent. solution of nitrate of silver injected. A few minutes afterwards urine was passed with great pain, so a warm bath and an opiate were ordered, which gave only temporary relief, the opium having to be repeated at night. The next day the patient's condition was the same as it had been before the injection. Three or four days afterwards a similar injection was given, with no better result. Four days later, as there was no improvement, the use of sublimate injections was commenced. The catheter was passed as far as the prostate, and forty-five grammes of a 2 per mille solution of sublimate in warm water were injected. This the patient was compelled to retain for three minutes; the subsequent micturition was very painful, but at night he was able to rest and retained his urine for three hours. The next day the urine was less turbid, and it was voided less frequently. His condition continued to improve for three days, when a second sublimate injection was given of double the quantity of solution. This occasioned some pain, but it quickly passed off and the patient was able to rest. In four days' time he requested to be discharged, as his urine was clear and he had no pain on micturition. Thus, the author remarks, two injections sufficed to cure completely an affection usually most obnoxious to treatment of an ordinary kind. The superiority of sublimate injections has shown itself in several cases of a somewhat analogous character in which he has employed it. These he proposes to publish and discuss on some future occasion.

MILK AND THROAT DISEASE IN CANTERBURY.

THE medical officer of health of Canterbury has reported a sudden outbreak of throat disease, which in eight days attacked no less than 231 persons, without fatal effects in any instance. So far as can be judged, the epidemic was due to milk, for of 160 houses served from the dairy which is in suspicion no less than were affected, and, as far as can be gathered, out of 3 houses supplied partly from the same dairy and partly by other milkmen 21 were affected. In the other instances of houses affected the persons in question seem almost exclusively to have been those who were either attacked late during the outbreak, and under circumstances which admit of their having derived the infection from antecedent cases, or else persons who may easily have partaken of the suspected milk elsewhere than in their own homes. So far as the reports on the case are, we trust, incomplete, for by far the most interesting feature of the case is the implied silence of animals in connexion with the outbreak, and the history as to this is as yet very

imperfect. Indeed, we only learn of a lamb in the suspected dairy premises having suffered "from sore-throat," and of cows having had "diarrhœa." The connexion now established between disease in the human subject and affections of a specific character in lower animals, and especially in cows, is of far too great importance to admit of such a case being passed over by such vague accounts in so far as these animals are concerned. It is to be hoped that skilled veterinary and pathological aid was secured, either through the Local Government Board or otherwise, and that a more complete report will be issued.

THE IRISH DIRECT REPRESENTATION.

A CORRESPONDENT says that "Dr. Jacob has neither resigned nor proposed to resign his corporation post." We certainly read Dr. Jacob's address differently. It is a point, however, on which there should be no doubt, and on which it is the duty of the Irish profession to inform themselves by direct appeal to Dr. Jacob. If the appeal is not satisfactory, there are other candidates who would well represent Irish practitioners, amongst them Mr. Thomas Laffan of Cashel, who is not only a general practitioner, but who has written on the subject of Medical Reform, and is the author of a Carmichael prize essay. There has never been in the Medical Council a representative of the provincial practitioners of Ireland, who play such a special and important part in that country. Mr. Laffan would meet this defect.

ASSOCIATION OF GERMAN NATURALISTS AND PHYSICIANS.

THE fifty-ninth annual meeting of the Association of German Naturalists and Physicians promises to be a very brilliant affair. It is to take place in Berlin from the 18th to the 24th of September, and the programme of its proceedings, issued under the authority of Professors Virchow and Hofmann, occupies six pages of our contemporary, the *Berliner Klinische Wochenschrift* (Aug. 16th). There are no fewer than thirty sections, and the number of contributions promised is very large.

THE DELICACY OF THE SENSE OF SMELL.

THE delicacy of the sense of smell in the dog, the shark, and insects is well recognised. Man is not greatly gifted with the olfactory sense compared with these; but if we may place reliance on the experiments of Professor Valentine, the delicacy is fairly great even in human beings. If we can sniff a tenth of a pint of air containing bromine in the proportion of a thirty thousandth of a milligramme, or the same quantity of air impregnated with the two millionth of a milligramme of sulphuretted hydrogen, we cannot mathematically have ground of complaint against our olfactory sense. Still less can this be the case if we can, as seems likely, detect the 230-millionth of a milligramme of sulphuretted alcohol or mercaptan.

THE SALE OF BAD EGGS.

MR. BARSTOW recently made an order at Clerkenwell for the destruction of 12,000 eggs seized in the parish of Clerkenwell by the officers of the Sanitary Authority. The vestry's solicitors have now informed them that no proceedings can be taken against the owner of the eggs, as no existing Act could be made to apply to this article of food. We are glad to learn that the vestry propose to seek an amendment of the law, for there is no reason to think that eggs when in a state of decomposition are less injurious to health than some other articles of food which cannot be exposed for sale without permit attaching to the vendor.

CHARTERHOUSE SCHOOL.

We observe with much satisfaction that steps are now to be taken to remedy the defective drainage of the houses occupied by some of the masters of the Charterhouse School. It seems to be acknowledged that these houses have not been effectually drained, and that although the masters have endeavoured to the best of their ability to remove this defect, they have failed to do so. It is of little importance to us whether this has been due to the refusal of the rural sanitary authority to provide an outfall for the drainage or to the successful opposition of the governors of Charterhouse to the Bill brought into Parliament by the Godalming authorities for a large and comprehensive system of drainage, including the school and masters' houses. The result has been unfortunate as regards the health of the boys. We are now assured that the difficulties have been overcome, and "that before the boys return from their summer holidays all danger from insufficient sewerage will be removed, and the house masters relieved from what has been a constant source of anxiety and expense to them." We trust this may be so, and that the governors may at the same time take the opportunity to modify the regulations affecting the position of the medical officer as regards sanitary recommendations, and require of him periodical reports to be made to themselves of the health of the school and of the conditions by which it is likely to be affected.

FOREIGN UNIVERSITY INTELLIGENCE.

DR. STEFFAL has been appointed Professor of Anatomy and Dr. Joseph Reinsberg Professor of Forensic Medicine in the Bohemian University of Prague.

Dr. von Dittel, Extraordinary Professor of Surgery in Vienna, is about to retire.

Professor Karl Schönborn, Director of the Surgical Clinic in Königsberg, has been unanimously elected by the Medical Faculty of Würzburg to the vacant Chair of Surgery in that university.

Dr. A. Wolff has been appointed Professor of Dermatology and Syphilis and Director of the Dermatological Clinic in Strasburg, in succession to Professor Wieger.

Professor Winckelmann has been appointed Professor of Physics in Jena, in place of Professor Sohnke, who has gone to Munich.

It is stated that the two old Swedish universities of Upsala and Lund are shortly to be supplemented by two new ones, situated in populous places—viz., Stockholm and Gothenburg.

ALLEGED INSUSCEPTIBILITY TO VACCINATION IN SPAIN.

ACCORDING to a local medical journal, the practitioners of Castellon in Valencia have nearly all observed during the present year a singular insusceptibility to vaccination from both calf lymph and human lymph obtained from a distance. This insusceptibility seems to be confined to no particular class of persons, and it is said to be observed in people who have been operated on by very different methods.

ANIMAL AUTOMATISM.

AUTOMATIC MAN (*l'Homme automate*) is the subject of an elaborate psychological dissertation by M. A. Fouillée in the *Revue des Deux Mondes* of August 1st. He opens with a reference to Huxley's criticism of Descartes' doctrine on the automatism of beasts. It is claimed for Descartes that under the name of *undulatio reflexa* he described the automatism of reflex actions, but he erred in placing man in a separate category. Experimental physiology has conclusively demonstrated that the reflex and automatic

functions of the spinal cord are common ni included; and it is reasonable to hope that with study of physiology and psychology as one science, profoundly interesting subject of animal automatism may better understood. Meanwhile thanks are due to M. Fouillée for a memoir rich in erudition and suggestiveness.

OUTBREAK OF ANTHRAX IN LEICESTERSHIRE.

AT a village (Arnesby) in the above county, some few miles from Leicester, there has been an outbreak on one farm of splenic apoplexy, which has proved fatal to some eight or ten beasts. On the 31st ult. a carcase of one of these was sent to the Leicester market, and the man in charge of it scratched his hand with the bone thereof, and died in a week from a severe attack of malignant pustule. At least two other men have suffered severely, also from the disease, who had to do with the killing of the animals. The veterinary inspector stated at the inquest on the fatal case that he never condemned beasts suffering from splenic apoplexy, as he considered them fit for food if thoroughly cooked. Some of the carcases were, it appears, sent to the London meat market, but were not, it is stated, sold there as human food.

CONGENITAL ABSENCE OF LEFT KIDNEY.

AT the Anatomical Society of Paris on April 9th, M. Albert Cayla presented specimens from the body of a child one year old, who had died in hospital of broncho-pneumonia. The child had a large congenital right inguinal hernia, but had no left kidney. The corresponding renal artery and vein were also absent, and there were only two openings in the bladder the urethra and right ureter. Both supra-renal capsules were present. The right kidney, enlarged and of ... lar shape, was in the normal position; it weighed sixty grammes, and measured nine centimetres in length and four and a half in width. The pelvis and ureter were dilated, their walls being thinned.

ANTISEPTIC PAPER DRESSING.

DR. DON ANTONIO MORALES PEREZ describes in the *Revista Médica* of Seville a simplified antiseptic or Listerian dressing, consisting of bibulous paper heated to 110° C. and soaked in a solution of carbolic acid, boracic acid, or corrosive sublimate. This is placed over the wound in about eight layers, and covered with sheet gutta-percha or mackintosh, the whole being secured by an indiarubber bandage. The writer claims for this dressing the advantages of cheapness and portability, and thinks it will be found very serviceable in the field and in small hospitals.

DIPHTHERIA AT WEST COWES.

DIPHTHERIA, which has occasionally been prevailing in West Cowes, has again broken out there, as many as five patients being stated to have been attacked in one house. The sanitary arrangements of the town are said to be, in many important respects, seriously defective. It is not very long since a medical inspector of the Local Government Board visited the place, and a strong representation has now again been presented to that Board for an exhaustive inquiry into the causes of the diphtheria. It is fully expected that the application will at once be acceded to.

CHYLOUS ASCITES.

M. L. STRAUS, in the *Archives de Physiologie* (Paris, May 15th), publishes an elaborate memoir on chylous ascites, and enunciates the following conclusions. A rare kind of ascites exists as the result of effusion of chyle into the peritoneal cavity, and therefore rightly named chylous ... Such effusion is always due to a lesion of, or ... in, the chyliferous vessels, the ganglia, or the ... duct. The irruption of chyle into the peritoneum ... due to transudation or to actual solution of con... of the chyle vessels, or of the thoracic duct. ... the chylous nature of the extravasation may be a ... with certainty by the following characters: the mi... l homogeneous appearance of the liquid, the extren... ness and regularity of the fatty emulsion which it con... s, its poverty in white and red globules, and the rapidit... of its reproduction with the same characters.

MR. GEORGE LAWSON, F.R.C.S., has been appointed Surgeon-Oculist in Ordinary to Her Majesty, in the place of Mr. W. Whi... Cooper, deceased.

ABSTRACT OF

THE BRADSHAWE LECTURE ON DIABETIC COMA.

Delivered at the Royal College of Physicians on Aug. 18th, 1886,

BY JULIUS DRESCHFELD, M.D., F.R.C.P.

Many Cases of Coma in Diabetes.—Sudden death in a comatose stat... frequently occurs in the course of diabetes; but it is necessary to distinguish between the various forms, for some are common to diabetes and other diseases, whilst the more strictly speaking diabetic coma presents features of extraordinary interest. *Cerebral hæmorrhage* may cause death in coma when diabetes is the disease from which the patient is suffering. *Acute croupous pneumonia* may cause death in diabetes without the usual symptoms of pulmonary inflammation, much in the same way as sometimes occurs in Bright's disease; the prominent phenomena being dyspnœa and coma. Dr. Dreschfeld considered, with Stokvis, that albuminuria is very frequent in diabetes, though the amount of urine passed may interfere with its detection. Death in coma may be the result of *interstitial nephritis* complicating diabetes. Mention was made of two cases of the kind in which headache, vomiting, and convulsions with marked dyspnœa rapidly developed and ended fatally; there was albuminuria, but no odour of acetone in the breath, and presence of aceto-acetic acid in the urine. Again, *intercurrent* affections may have a resemblance to true diabetic coma. Death from slight operations in diabetic subjects may result from paralysis of the heart-muscle or nerve-centres. One case of urethral stricture was referred to, in which death occurred ten hours after the necessary operation; aceto-acetic acid was not detected in the urine; the adrenal was hypertrophied and dilated; the heart free from fatty degeneration. This might be regarded as a case of catheter fever occurring in a diabetic.

Three kinds of Diabetic Coma.—In 1881, Dr. Dreschfeld read a paper before the Midland Medical Society in which he differentiated three chief forms of diabetic coma. Twelve months after Frerichs expounded the same views in the *Deutsch. Zeitsch. für Klin. Med.*, and adopted an identical classification, whilst distinguishing more clearly between the first and other forms.

Dr. Dreschfeld next proceeded to give an account of the three forms. The first, called *diabetic collapse*, which had been recognised by Prout, consisted in the development of drowsiness with extreme dryness of the surface, quick pulse, and shallow breath; death occurs with falling temperature in from ten to twenty hours. The urine, which may be passed voluntarily during the early stage, contains from 5 to 8 per cent. of sugar, but aceto-acetic acid, and a little albumen. Active delirium or convulsions are absent; the pupils, though sluggish, react to light. The necropsy reveals no marked naked-eye changes; the body is usually stout and well-formed; the heart has been found to be fattily degenerated, or its fibres in a state of granular degeneration; whilst the liver has presented greyish patches of fatty metamorphosis. This is most frequent in people above forty, who have had diabetes for some time—cases

turn of duty has entire command of his ship. This gentleman is a complete colour-blind, and is still sailing as second mate. In justice to the steam-ship companies I must remark that they are unaware of his defect. I could mention other illustrative cases, but I have I think brought forward sufficient proof, not only of a danger that does exist, but also that adequate care is not taken, in the case of sailors, to guard against that danger. And the danger is no my ..., though many are inclined to think that it is much exag...erated. The number of sailors in Liverpool has been c...culated for me by Dr. Hope, the assistant medical off...r of health, to be 27,136. Taking 3·40 per cent.—the per ...ntage found in the 3087 cases—to be colour-blind, we hav... a total of 922·99 men in that line of life who have not ar... accurate colour perception.

In a very able article[4] Dr. Brailey points out that the regulation side lights on a vessel, the red and the green, should be recognised in clear weather at a distance of two miles, and that in the case of two vessels meeting at night, until therefore they are within two miles ... each other, they can get no indication of their relative po...itions. That if the night is not clear or the lights badly tri...med, the distance at which the lights can be seen is grea... diminished. Supposing two steamers going at a rate of t...elve miles an hour (the Holyhead boats travel at the rate ...f twenty), he points out that they would meet in five m...utes, a short enough time for a course to be altered. ...lf therefore there is any hesitation on the part of those ... command, a calamity such as has recently occurred m... take place. The subject is one that may be worked at ... all, and one that would be found of interest by all, and ... the medical profession have generally been the means o... pointing out existing dangers, so in this case I expect it i... only through them that this subject will attain the attentio... due to it.

HÆMATURIA FOLLOWED BY R...TENTION OF URINE.

By HENRY GRAMSHAW, L.R.C.P.L... M.R.C.S.

E. R——, aged sixty-nine, of Lowestof... a stout, fairly healthy-looking tradesman, called at my s... gery to consult me on Sept. 5th, 1880. He complained o... some difficulty in micturition at night, and remarked t... t the fluid he voided was dark in character, and somew... t diminished in quantity. I gave him a purgative, and ... escribed a gallic acid mixture with henbane and infusio... of buchu. He called again on the 7th, bringing wit... him a bottle of coffee-ground-looking fluid, evidently ...ine, mixed with blood, and said he felt a little better, ... rested longer at night, since taking the medicine. On ...e 9th he called to say he was much better, and that the ...ine was almost clear again. On Friday, the 10th, he presented himself with a less favourable report, and brought more urine, charged with blood, as before. He has been continuing his medicine, with the addition of some acetate of ...ad and opium pills, but without experiencing much bene...t from it. He had rather imprudently taken a railway journey to Yarmouth on the Thursday, and sat up late; ...rther on in the day he sent for me to visit him at his ho...e, but being absent at the time, my assistant went, and, finding that the patient was unable to micturate, he passed a No. 8 gum-elastic catheter, and drew off about four ounces of bloody urine, which apparently afforded him much relief. This was at 5 o'clock. An hour later I saw him myself, and found him walking about the room in great distress. I passed a catheter, and drew off about a teacupful of bloody fluid. I tied the catheter into the bladder, and left him. Between 12 and 1 o'clock I was sent for again to see the patient, and my friend Mr. Clubbe kindly met me in consultation. We decided to give him a mixture containing opium and ergot, and to leave the catheter *in situ*; there was a small quantity of fluid oozing from it. On Saturday, the 11th, I found the patient had passed a tolerable night, with occasional sharp paroxysms of pain. The cloths and bedclothes were saturated with blood and urine, which had flowed down the catheter. I had them removed, and placed the end of the catheter into a glass bottle to ascertain the amount actually passing. At my ... I found that about eight ounces had esc... I emptied the bottle, and replaced the catheter. ...t 9 o'clock the same evening Mr. Clubbe met me ...ain. No urine had passed since my last visit, a space of eight hours, and we decided to withdraw the instrument, expecting it had got plugged, and to substitute a fresh one. We passed both gum elastic and silver prostatic catheters consecutively into the bladder, but no fluid came away, and we felt a little doubtful if by any chance a false passage had been made, though it did not appear so, as no difficulty was experienced with the catheter.

Not to be tedious, I will briefly say that during the next day (Sunday) Mr. Clubbe and I made several attempts to empty the bladder, but failed to do so, and we were a little surprised to find, as time passed on, that our patient's symptoms were not more urgent than they appeared to be, as the retention was complete. The pain, such as it was, he felt principally at the end of the penis, there being comparatively little about the vesical region. The grave aspect of affairs led us to deliberate on the next best mode of procedure; and we asked ourselves the question if it would be wise to proceed to puncture the bladder per rectum or otherwise. Having laid the facts before the relatives, I counselled them to allow me to telegraph for Mr. Cadge of Norwich to assist us with his opinion and advice in the emergency. Consent being given, that gentleman came over and saw the patient, with Mr. Clubbe and myself, at half-past ten on Monday the 13th. Just before his arrival a little additional light was thrown on the case in consequence of the patient having passed in a clot of blood about twelve small calculi. The history of the case up to the present time having been laid before Mr. Cadge, he at once gave it as his opinion that the patient's bladder was fully distended and blocked up with clotted blood, and that in all probability when catheterism was performed, the catheter went fairly into the bladder, piercing the blood-clot, which was too solid to flow down it. He said he was strongly averse to puncturing the bladder by the rectum in the case of an elderly, fat man, with prostatic enlargement, as it would probably be a procedure attended with no benefit, and, if need be, he should prefer either to puncture the bladder above the pubes or to asp...ate it—which latter might be considered a more new-fashioned plan of procedure; but before electing to undertake either operation, he would try what could be done *per vias naturales*—i.e., by the urethra itself.

Accordingly Mr. Cadge passed a No. 8 (with an unusually large eye), and afterwards a No. 10, into the bladder without much difficulty. A very little currant-jelly-like fluid escaped. After a long and most painstaking process of breaking up the clot in the catheter with a stilette, and gradually and judiciously forcing the clot down the catheter by firm and yet gentle pressure on the bladder, there was discharged a chamber utensil half full of clotted blood, mixed with ammoniacal-smelling urine, giving the patient substantial relief. The proceeding itself involved fully two hours of patient and skilled manipulation on the part of the operator, at the end of which time the patient fell back and slept comfortably for several hours. At 9 P.M. a similar process had to be repeated by Mr. Clubbe and myself.

Sept. 14th.—10.30 A.M.: Patient has had a very restless night; complains of more intolerance of the loaded bladder than he did previously. When the catheter is passed clot and thick treacly liquid comes at first, but little else; aided, however, by Clover's catheter with elastic suction-bottle, after first throwing into the bladder a little warm water, I got the patient to stand up, when a stream of bloody urine flowed down the catheter, amounting to twenty ounces or more. 8 P.M.: Used Clover's catheter again this evening. Patient passed more urine than he has yet done, and of a better colour and greater fluidity. There has also been free action of the bowels. The patient can take only milk. Gave him an opiate at night.—15th: Patient better; appetite returning. A considerable quantity of bloody urine withdrawn three times during the day by catheter. Ordered camphor and hyoscyamus, five grains of each, at bedtime, and to take the following three times a day: Solution of dilute sesquichloride of iron, twelve minims; water to one ounce. From this date the patient got slowly better, requiring catheterism three times a day for nearly a month, after which time he quite regained his usual health.

Remarks.—I have been tempted to give the details of this case rather fully, because it is the sort of case one might meet with any day in practice, and would always give the

[4] Brit. Med. Jour...

surgeon in attendance considerable [illegible] also exemplifies the advantages of patience and [illegible]ence. I gathered from Mr. Cadge's remarks that in all cases where retention of urine from the presence of a large quantity of clotted blood in the bladder took place he would be disposed to temporise, believing sooner or later that the clot would liquefy and break down, and be removable by means of a good-sized large-eyed catheter.

Walton-on-the-Naze.

THE SIGNIFICANCE AND TREATMENT OF CERTAIN FORMS OF ALBUMINURIA.

By A. G. AULD, M.D.

Acute Albuminuria.—Acute albuminuria or acute nephritis is a remarkable disease. Excepting its occurrence from the scarlatinal or other specific poison, it is in the great majority of cases ascribed to "cold and wet." Yet of a hundred cases of exposure to these agencies probably not more than one will be visited by this disease. Again, in scarlatina no adequate reasons can be given for its development in any particular case. It must therefore be confessed that its intrinsic causes are unknown; and not only so, but likewise the *modus operandi* of these causes *ab initio*.

Looking then, at the known facts, increase of arterial tension is the first observable symptom. Occasionally there is hæmoglobinuria. The invasion may take place insidiously, unattended with any constitutional disturbances perceptible to the subject, who may be suffering from debility; or sudden and fierce, giving rise to grave constitutional states. In the asthenic form, dropsy is usually the first symptom noticed by the patient if his attention be not previously drawn to the state of his urine. But, however established, uræmia is equally liable to supervene, and may even be the first symptom to give the alarm.

These modes of onset of this disease are not without parallel. For instance, it is known that acute pneumonia, though in the majority of instances having a sudden onset, may yet be creeping into a lung, and become pretty extensively established before the individual be sufficiently ill to think of leaving off work. There are also other striking points of resemblance in the natural histories of these diseases.

I suppose there is no disease of which it may be more truly said than of nephritis, that it spurns our artificial medication. Many persons pass safely through it without ever seeking medical aid; and when treated, if happily it should disappear, that result is of course by many set down in orthodox fashion to the particular remedy or remedies employed. It is not so very long since many highly respectable practitioners prescribed a course of mercury in this disease, and, *mirabile dictu!* very often with the result of a cure. It is a good thing that Nature still works as heretofore.

The eminent Sydenham, treating of the dropsy, remarks that the curative indications are to evacuate the water and to strengthen the blood.[1] The first of these he fulfilled by speedy and smart purging, provided the patient was strong if of a weak habit, he found purgatives harmful, and resorted to diuretics and strengthening medicines. This mode of treatment was that generally adopted up to the time of Christison. Since then diuretics have fallen into comparative disuse, while the purgatives have been retained, which, together with hot baths, starvation diet, the imbibition of large quantities of water or other harmless fluid, and occasionally bleeding, form the cardinal measures now in use.

Unfortunately it has become the practice of many to adopt most or all of these heroic measures in every case of acute nephritis. It is said that diaphoretics and purgatives do the work of the kidney. That to some extent they do so cannot be gainsaid. They do produce a transient and superficial relief, but it is equally certain that their indiscriminate use is often productive of the greatest harm, especially if indulged in for any length of time. There are doubtless contingencies wherein one or other of these heroic measures are called for; where, namely, pyrexia runs high, where vascular tension overleaps the bounds of safety, where the march of uræmic symptoms is unchecked by the natural means, or where the advancing tide of œdema threatens to invade the vital organs. But each case is to be dealt with on its own merits, and the weakly will often quickly recover on tonic treatment, while irretrievable damage might be inflicted by any such exhausting processes as a course of purgatives and hot baths.

Whatever benefits are supposed to accrue from the energetic means so universally adopted, it is certain that physiologically they are antagonistic. The hot bath causes a great increase of the general blood-pressure and of the temperature, a bounding heart, with distended vessels and injected capillaries. Purgatives and antiphlogistics cause lowering of the blood-pressure and of the temperature and a depressed heart; while fluids imbibed in quantity heighten pressure and dilute the blood. I think, to pursue such a course of treatment can scarcely be justified on scientific grounds. Where is the *rationale* of placing cupping-glasses over the loins and then filling the kidneys with blood, of abstracting the water of the blood and then pouring water into it?

There is one of these agents, however, which must be discussed more in detail, and that is the hot bath. Senator has proved that when the temperature of an animal is raised by from 1·5° to 3° C. albuminuria results; and if the temperature be very rapidly raised to an extreme degree, blood and often hyaline and granular casts are present in the urine.[2] Albuminuria also occurs in the human subject from a very high bodily temperature. The kidneys being greatly distended with blood, rupture of capillaries is liable to take place. Yet hot-water baths, sufficient to produce these effects in some measure, are employed for the cure of inflammation of the kidneys. The warm bath, with its many beneficial effects, is set aside in favour of baths which cause an enormous rapidity of the pulse-rate and respiration, and sustain a great height of temperature; indeed, lately a St. Petersburg physician for these very reasons strongly advocates the use of hot water in preference to hot air or wet packing.[3] It is also an interesting fact that cases of scarlatinal albuminuria are most frequent during hot, relaxing weather, as the statistics of the London Fever Hospital show, and very frequently apparently healthy persons pass little albumen in these circumstances. This being so, another method must be sought for the production of diaphoresis, and nothing is more admirably fitted for this purpose than the hypodermic injection of pilocarpine. Given in doses of from a quarter to a third of a grain, profuse diaphoresis is induced, without any vascular stimulation, but, on the other hand, with fall of tension. If, however, smaller doses are given, there is an initial stage of stimulation, which quickly passes off. Not only is this the best remedy for dropsy, but also for threatened uræmia and for uræmic convulsions, should purging prove ineffectual.

So far, then, as I have observed, I should prefer to adopt in the first instance a somewhat expectant plan of treatment in this affection. In the early stages, should no urgent symptom arise, small doses of aconite will suffice, with due attention to diet, which should be fairly nourishing and include abundance of milk. Should the disease threaten to become subacute, abundant nourishment, with cod-liver oil and iron, should be administered. I could relate several instances, some of them amusing, of patients who were kept in bed half starved, and steamed for weeks, with but little amelioration of their symptoms, who got up and returned to their usual diet and modes of living, and speedily recovered.

Acute albuminuria may terminate suddenly or gradually. Complete recovery may ensue after the dropsy has been six months or even a year established; and it may occur many times in the course of a life without causing any chronic affection of the kidneys. If, however, the disease should attack one who has got diseased bloodvessels, however slight, he can never perfectly recover.

Albuminuria of Debility.—If a medical man examines the urine of all who may consult him without reference to any disease of the kidney, he will frequently find albumen. In the majority of cases he will also be able to discover its cause. I wish to notice here the form of albuminuria associated with debility without any renal lesion. A great many cases of transient albuminuria and so-called cyclic albuminuria, which are variously ascribed to impure blood, slight congestions from cold, dyspepsia, nervousness, and other causes, also called albuminuria of adolescents, may shortly be said to be due to debility. In a strong person, a nervous

[1] Works, edited by Swan, pp. 593-595.

[2] Senator on Albuminuria (New Sydenham Society), pp. 42-50.

[3] THE LANCET, 1885, vol. ii, p. 1016.

shock, or gymnastic exercise, or a night's dissipation will not likely be followed by albuminuria. But if the tissues be vitiated, various states of the nerves and vessels arise which readily explain its occurrence. It will thus be found sometimes due to the mere nervousness many persons experience on coming into the consulting-room. By systematically examining the urine of as many patients as possible, I have been fortunate enough to discover a few presenting this form of albuminuria, but cannot say that I have observed anything which justifies the application of the term cyclic to them, unless it be the absence, as a rule, of any albumen in the evening and morning. The albuminuria appears with the exciting cause, and varies with the general health. It is doubtless due either to spasm or paralytic dilatation of the renal vessels. "Whenever," says Hutchinson, "the circulation is specially liable to reflex derangements, and congestions or their opposite occur with unusual facility, we are safe in declaring that the tone is low. It is part of the nervous system to duly regulate the supply of blood to various parts, to prevent local arterial spasm, and under the varying conditions of daily life to maintain the normal balance of the circulation. When this power is deficient, the various causes of disease act with increased effect."[4]

Regarding the treatment of these cases I have seen the albumen entirely disappear after a course of cod-liver oil. Abundant nourishment should be taken and a good amount of exercise. There appears to be nothing so very remarkable about them as some would suppose, and it is not improbable that a little albumen is now and then passed by everyone in sufficient quantity to be easily recognised by ordinary tests.

Wick, N.B.

MEASLES DURING VACCINATION.

By A. K. CHALMERS, M.B.,

LATE PHYSICIAN-SUPERINTENDENT, JOINT BURGHS FEVER HOSPITAL, MARYHILL, GLASGOW.

It seldom happens that the date of exposure to the contagion of measles can be fixed so accurately as in the following series of cases.

On April 20th, B——, a child, two months old, was vaccinated, and on that day week had two well-developed vesicles. It seemed in perfect health, and three children were vaccinated from it by the direct method. On the following day, after a few hours' fretting, a measles rash appeared and followed a normal course. There were no distinctive premonitory symptoms, and the course of the vaccine vesicles was not affected by the measles. Of the three children vaccinated from this infant, one, F., five months old, developed a typical measles eruption on the afternoon of the eighth day of vaccination (May 7th). No stage of premonitory symptoms, and course of vaccine vesicles unaltered. Another of the three, H., five months old, had some lacrymation on May 4th (one week after vaccination), was restless and sneezing during the following day, and on May 6th presented a blotchy and ill-developed rash of measles on the trunk and limbs. The vaccine areola here was of considerable size and hardness. The third child (S.) displayed a papular eruption (vaccine lichen) in the second week, but no measles, and may now (three weeks after exposure) be assumed to have escaped the infection. In connexion with the child H., another case arose in an infant of a few days. This patient, the child of a neighbour, was born on April 26th. On May 6th it vomited, and on the 7th was completely covered with a typical rash of measles, which followed the course of a normal one in older children. From May 2nd a hoarse "measly" cough was present. When the child first mentioned developed measles, it became of importance to watch the probable inception of the disease in the others. They were children of families living widely apart, and only brought in contact for vaccination. The vaccinifer, as afterward appeared, was then in the pre-eruptive stage of measles, but no catarrhal symptoms had developed. What part, if any, would the lymph play? Could it act as carrier of poison from a source which had given no indication of being contaminated? If the children vaccinated from this one became infected, how had the contagion reached them.

The fourth case related, in the child of eleven days, suggests, if it does not determine, the manner of infection. [Th]e followed, within twenty-four hours, its appearance on the neighbour's child (H.); and unless the incubation period of measles can be reduced to a vanishing-point, these two cases have only an accidental relationship. Indeed, this youngest child seems to come within the primary circle of infection, and to have derived its infection indirectly from the source which affected the children F. and H. How far, however, the first case may be held as causing the others is uncertain. We recognise the pre-eruptive stage of measles as probably the most infectious, but catarrhal symptoms have been held necessary to fix the beginning of the infective period. This child had no such stage; the eruption was amongst the earliest symptoms. The other children of its family went through an epidemic of measles about six months before. In the interval they removed from the house they then occupied, but carried the contagion with them. A passing depression of the child's system, consequent on vaccination, supplies the necessary fuel, and the poison awakens to fresh activity. But unless we regard the clothing of this child or its mother as containing the contagion which infected two of the children vaccinated from it, and by transmission, in the clothing of the child H. or its mother, reached the newly born infant, we must accept an infective period, preceding the eruption of measles, which is non-catarrhal, and has no symptoms by which it can be recognised. The child which escaped infection is probably an example of the possibility of pure cultivation of vaccine virus in an infectional medium.

Mossend, Lanarkshire.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

FISH AS AN INVALID DIET.

By J. STUART NAIRNE, F.F.P.S.G.,

SURGEON TO THE GLASGOW SAMARITAN HOSPITAL FOR WOMEN.

In the summer of the year 1879 I attended a young gentleman in Crosshill suffering from typhoid fever. The course of the disease was very sharp, but he came favourably through it; and when I left for my holidays, four weeks after the commencement of the disease, he was regarded both by myself and another medical man as convalescing. Less care was then exercised with regard to regulating his diet, and the medical attendant called only occasionally to see him. He partook of fresh white fish, and of only a small piece for breakfast. During the same evening my friend was called in hurriedly to see him. There had been a sudden rise in temperature, a relapse of the fever, with dark-coloured stools, and he died in a few days.

Last summer the sister of a medical friend in the country took ill of typhoid fever of a lingering type, with a not very exalted temperature. She seemed to be convalescing favourably, although slowly, when she was given a little fresh fish, boiled. The fever assumed an acute form, she suffered from pains in the bowels, followed by dark-coloured stools, and she died in about ten days.

A little boy in Pollokshields had a mild attack of gastric fever. The temperature was never very high, langnor, debility, and wasting being the prominent symptoms. At the end of three weeks he seemed to be progressing favourably, and I had diminished my attendance on him. He had a small piece of fish given him, which was immediately followed by a relapse of the fever, an aggravation of all the symptoms, and pain in the abdomen. It was fully three months before he recovered, although previously to his taking the fish I could have pronounced him to be well.

A young lady was suffering from hæmatemesis, the result probably of a gastric ulcer. She was reduced to an excessive degree of pallor. Her diet was regulated, and she took Morson's pepsine. She seemed to make a good recovery, and I ceased my attendance for several days. In the interval she had broken through the regulations for her diet, and partook of a little fresh fish, as being, she said, a very light diet. She afterwards became suddenly ill, and vomited a large quantity of blood; she also passed dark clotted blood

An old gentleman in Mount Florida [illegible] in what was presumably malignant disease of the pylorus. He both vomited and passed dark blood at stool. Palliative measures were adopted, and his diet was regulated. Fish, which had not been particularly forbidden, was partaken of one day, and this was followed by excessive vomiting of blood and by death.

A lady in Glasgow is at present suffering from what has been variously diagnosed as disease of the stomach, pylorus, omentum, and liver. At any rate she is jaundiced, wasted, and subject to severe pains and sickness shortly after taking food. She feels frequently very sick, vomits frothy fluid and dark bilious matter, and occasionally passes decomposing, loose, bloody, dark matter of a most offensive smell. On every occasion on which she has partaken of fish these symptoms have been aggravated if present, and have been brought on if absent.

Cases such as these have been continually cropping up and causing great anxiety. It seemed to me that, under any circumstances of debility, fish, instead of being a genial diet, is a very dangerous one, and I had got into the routine practice of almost always forbidding it; but I have been induced to put these cases on record because I believe now that it is the preparation, the cooking, of the fish that is at fault, and not the fish itself. Recently I have been able to see all the recognised benefits of this diet from using it steamed, and not boiled. And for this hint I am indebted to the intelligence of a patient. I had, as usual, forbidden fish to be eaten, explaining my reasons. I was told that fish steamed, as was done in that house, was as tender as could be, and never disagreed with them. The fish so prepared was partaken of both with relish and benefit. I got a steamer for myself, have recommended this plan of cookery to my patients, and have had satisfactory results. Dieting is the half, and sometimes the best half, of medical treatment; and, perhaps a little to my chagrin, I find that this system of preparing fish has been specially recommended by various schools of cookery. Perhaps, however, many medical men, like myself, may be unaware of the fact, simple as it is, that boiled fish, fried fish, and almost any other kind of cooked fish, are all inferior in digestibility to steamed fish. The kettle[1] I have used is a simple and efficient steamer. The fish is never touched from the moment it is put on the drainer in the kettle till it is cooked, and the drainer is so constructed that it can be removed from the kettle with the fish and placed upon the dish for the table.

I have ventured to put these few cases on record both on account of the dissatisfaction I have had formerly and the satisfaction I have now in ordering a cheap, nourishing diet.

Glasgow.

NOTE ON A RARE DISLOCATION OF THE ELBOW-JOINT.

By C. GEORGE BATTISCOMBE, M.B., C.M. Aber.

ON April 9th I was called to see a gentleman who had met with an accident while hunting. I found him lying in a field, and was told that his horse, after jumping a fence with a long drop, had fallen over backwards upon his right arm and leg. He complained of great pain in the elbow-joint on the slightest movement. It was very much altered in shape, and evidently severely injured. I secured the arm in a sling, and had him removed to the Cottage Hospital (Chislehurst, Sidcup, and Cray Valley), which was close by.

On his arrival at the hospital I examined the arm, and found it in the following condition. The forearm was fixed at rather more than a right angle to the arm; all power of natural movement of the elbow-joint was lost; and any attempt at forcible movement caused great pain. The hand was partially pronated, but on turning it pronation and supination could be readily performed. The elbow-joint appeared too wide from within outwards and from before backwards; it presented two prominences below, an inner and outer, and one above the latter, which projected backwards and was continuous with the forearm. The inner angle of the joint was too high, so that the arm appeared to be shortened. There being no amount of swelling, the following points could be clearly made out. The ulna and olecranon were missing from their natural position in relation to the humerus, the two condyles of which could be distinctly felt with the notch between them. The ulna and olecranon were resting fully half an inch above the external condyle of the humerus, the elbow projecting about an inch beyond the latter. The radius could be felt above with its head resting against the outer border of the humerus. It was not separated from the ulna, and rotated readily on pronating and supinating the hand.

I put the patient under chloroform, and carefully examined for any fracture. I could find none whatever, and concluded that it was a case of complete dislocation outwards of both bones of the forearm. I then proceeded to reduce the dislocation. Grasping the forearm with one hand, and the elbow with the fingers of the other, I pulled it steadily downwards, endeavouring to get the olecranon over the external condyle. It took some minutes to do this, and required a good deal of force. Then, holding the olecranon below the condyle with the left hand, I seized the forearm lower down and used it as a lever, and while forcibly extending the forearm I rotated it outwards. On continuing the extension, the olecranon suddenly slipped into its natural position. The joint immediately answered to all its proper movements, but when left alone tended slightly to return. I fixed it at a right angle on a posterior angular splint.

When I called in the evening the patient was free from pain, and complained only of a feeling of numbness in the arm and hand of the injured side. The next morning, when I arrived at the hospital, he had gone home; but I ascertained that, beyond the numbness and a little swelling, he was very comfortable. A week afterwards he was doing well, could move the joint pretty freely, and was free from pain.

Complete lateral dislocation of both the bones of the forearm is, I believe, extremely rare. I have seen no description of it, though it is mentioned in several surgical works.

HYSTERIA OR TETANUS?

By JAMES LAFFAN, L.R.C.S.I.

THE following case presents some interesting features:—

On Easter Sunday last I was hurriedly called to attend a young girl, a servant, who had been accidentally shot. I found her lying on a bed bleeding profusely from a large ragged wound, which seemed to have carried away the greater part of her right cheek. She had received the contents of a gun—a large charge of small (No. 6) shot—discharged at a distance of not more than four feet. It being late in the evening, I satisfied myself that there was no fracture of importance, and merely arrested the hæmorrhage.

Next day I found that the charge of shot had struck between the molar teeth of the upper and lower jaws, which must have been in apposition at the moment. The teeth were uninjured. The pellets glancing off the teeth had distributed themselves in every direction. Some had gone almost vertically upwards, breaking off the inner end of the zygoma, and finally lodging themselves beneath the eyelid in the inner angle of the orbit. Others had been deflected downwards, others back as far as the parotid gland, others again forward to the angle of the mouth. A few had penetrated deeply through the canine fossa, and lodged themselves beneath the zygoma. All the muscles of this side of the face were more or less bruised and lacerated, and there was much sloughing.

After three days' incessant poulticing and syringing all the sloughs and foreign bodies came away, leaving a clean, healthy wound. I extracted in all 311 shot. On the fifth day the patient complained of a good deal of pain about the jaw, also of stiffness in that region (the latter was attributed to the bandages), and of a burning pain in the stomach. On the sixth day she was seized with violent tetanoid convulsions. I was sent for, and on my arrival found her in a state of perfect rigidity, moaning with pain. Opisthotonos was well marked. I gave chloroform, and after a little while the spasms ceased. I then ordered her full doses of bromide of potash and chloral hydrate. She was quiet until the next day, when she was again seized with similar symptoms. They again yielded to chloroform. She was attacked again twice during the night of that day, but much less violently. Her condition was one of stupor now, from the [illegible] hypnotics. The following day

and as far as possible the intestine. When the transversalis fascia was reached it was seen bulging forward with fluid behind. When the opening was completed a strong rush of blood-stained fluid took place. The exploring hand detected a rupture on the upper and posterior part of the bladder wall. It was about two inches and a half in length, and ran from above downwards and to the left. No injury to the intestine could be made out, and no material similar to that which came from the bladder was found. The abdomen was thoroughly washed out with hot water, a glass drainage-tube passed into Douglas's pouch, and the rest of the wound was closed by gut sutures. A drainage-tube was passed into the bladder through the perineal wound.

After the operation the sickness still continued. The pulse was weak and rapid, respiration also rapid; but the patient stated that his pain was very much less than before operation. Urine passed freely by the tube in the perineum, and a small quantity of bloody serum was from time to time sucked up through the glass tube from the abdominal cavity. Next day (Friday, May 7th), the patient's pulse had improved, and the pain was still less. There was still some distension of the abdomen, with tenderness on pressure; but the patient passed flatus freely. The temperature, normal at midday, was 99·6° F. at night, and the urine was flowing freely from the perineal wound. Towards evening it was observed that the flow of urine was lessening, and after midnight it ceased entirely. The sickness still continued, and nutrient enemata were given throughout the day. The amount of serum drawn off from the abdomen was less, and there were some lymphy flakes in the discharge

The following day, May 8th, the suppression of urine still continued; the patient was visibly weaker, and was still vomiting. Respiration shallow, rapid, entirely thoracic; pulse weak (120). No pain except on vomiting. During the day the following medicine was repeated every two hours: One drachm of sulphate of magnesia, ten grains of carbonate of magnesia, in half an ounce of peppermint water. In the afternoon the sickness had very greatly abated, the patient being able to tolerate small quantities of iced champagne by the mouth. By the evening the patient's condition had somewhat improved, and the pulse was less rapid and fuller. The suppression of urine still continued, though constant hot fomentations were applied to the loins, and repeated dry cupping was resorted to.

9th.—Early on Sunday morning the patient became rapidly more collapsed, with cold extremities and scarcely perceptible pulse. Ether was given hypodermically and the amount of champagne increased, and the patient rallied for a few hours, but in the evening he again sank, and complained of increased abdominal pain. About 8 P.M. one-third of a grain of nitrate of pilocarpine with twenty minims of sulphate of ether was given hypodermically, but produced no sweating, only profuse salivation. The patient died at 9 P.M.

At the post-mortem examination the body presented the following appearance:—There was very little peritonitis, but around the drainage-tube some matting together of the intestines. There was a considerable effusion of blood behind the peritoneum on the left side, extending as high as the left kidney. No communication existed between the rectum and the bladder, and no rupture of the bowel at any point. The bladder wall was thickened and fibrous, with numerous hæmorrhages into the submucous tissue. There was in the posterior wall to the right side a rupture, about two inches in length on the peritoneal and an inch on the mucous aspect of the bladder. The margins of the wound were beginning to unite, but the adhesions were soft and easily broken down. A dense mass of cicatricial tissue was seen in the urethral wall in front of the bulb, at the seat of the stricture, and several old false passages. The kidneys were pale, cortex thickened, capsule slightly adherent at points, indicating probably some interstitial change with fatty degeneration of the epithelium of the tubules. Liver fatty; hypostatic congestion of both lungs; some thickening of the wall of the left ventricle of the heart; valves competent.

A MUNIFICENT GRATUITY.—A gratuity of £10,000 has been granted from the Bavarian Civil List to the widow of Professor Guden of Munich, [illegible] with the late King of Bavaria in the lake, [illegible] left a family of eleven children.

Investigations into some Morbid Cardiac Conditions. By WILLIAM RUSSELL, M.D., M.R.C.P. Edin. Edinburgh: Bell and Bradfute. 1886.

THERE are few subjects more interesting to the clinical observer, or which have given rise to greater controversy, than the correct interpretation of the cardio-vascular phenomena that characterise the anæmic state. This subject forms the major part of the volume before us, and we may honestly say that we have seldom had it presented in a clearer light. It is introduced by a historical retrospect upon the question of inorganic murmurs, and it is satisfactory to find that the share taken by Hope, too often overlooked, is fully recognised. Dr. Russell brings the results of observations in the post-mortem room to disprove the statement of Walshe and Balfour that the pulsation in the second left interspace is due to the left auricle. He shows conclusively—by cardiographic tracings as well as by morbid anatomy—that such pulsation is of right ventricular origin. Indeed, he assigns a far larger share to the right side of the heart than is usually given it, and we must think that he does well in reminding us that we have to reckon with two sides rather than one. The steps of his argument, supported by numerous observations—that the basic murmur in chlorosis is a tricuspid regurgitant murmur, and that no arterial murmur (other than an artificial one, produced by pressure of the stethoscope) exists,—must be followed in the work itself, for we cannot do justice to it here. As to venous murmurs, he is of opinion that the quality of the blood is a factor in their production, but that more or less constriction of the vessels is the essential element. There is also an interesting chapter upon tricuspid murmur and mitral stenosis, and one upon the differential diagnosis of vegetative or verrucose endocarditis. The book is one which shows the author to be a careful clinical observer, and it cannot fail to be read with profit both for the facts it brings to light and for the ideas which it suggests. He has chosen topics which rank among the most debatable as well as those which are least studied in cardiac disease, and he has materially added to our knowledge of them.

Medical Missions: their Place and Power. By JOHN LOWE, F.R.C.S.E., Secretary of the Edinburgh Medical Missionary Society, and Superintendent of its Training Institutions. With Introduction by Sir WILLIAM MUIR, K.C.S.I., LL.D., D.C.L., late Lieutenant-Governor, North-West Provinces of India, and Principal of the University of Edinburgh. London: T. Fisher Unwin. 1886.

MR. LOWE'S book is one that was much needed, and for writing which his experience as a medical missionary in Travancore and his long connexion with the Edinburgh Medical Missionary Society well fit him. The medical mission work and the training of medical men for it, as far as Great Britain is concerned, have had very much to do with Edinburgh, and to give an account of the work of the Edinburgh Medical Society is virtually to survey the whole field. The Edinburgh movement began with Dr. Abercrombie, who was chosen President of the Society, which originated in a meeting in his house, at which an account was given of the work of Dr. Parker, an American medical missionary, who had laboured long and successfully in China. Charity begins at home, and so it was with this good movement. Dr. Handyside, an anatomist and surgeon of great accomplishment, obeyed the request of the city missionary to see bad cases among the poor of the Cowgate. Then the poor of Ireland were the first objects of attention of the Society. Now the Society has a local institution for the training of medical

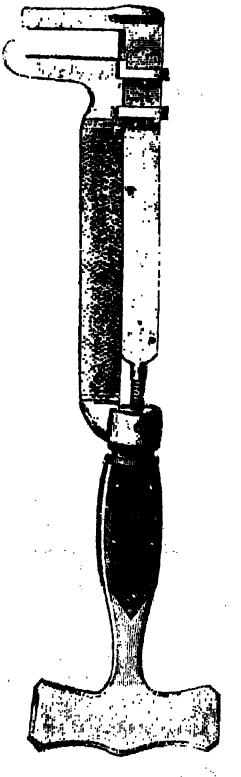
missionaries, to which all the great societies refer, and from which some of the best medical missionaries have hailed. It cannot be too clearly realised, however, that to the piety of its great local physicians and surgeons Edinburgh owes the creation and success of the Society. Abercrombie, Alison, Handyside, Miller, Coldstream, and Benjamin Bell are classical names in Edinburgh medical history, and they were all active promoters of this Divine cause. If anyone doubts the impression for good made on uncivilised or unchristianised nations, he has only to read this book, though it by no means exhausts the statement of medical work done or impression made. One very excellent feature of Mr. Lowe's book is his insistance on the thorough and complete training and qualification of those, whether men or women, who go out to do medical missionary work. Their surgical and obstetrical training should be even more complete than that of average practitioners, seeing that they have no help in consultation or co-operation with others, as in difficult cases at home. The rapid progress of this Society is gratifying. In 1861 its income was £590; in 1871, £1314; in 1881, £5506; while during the last decade £15,000 were raised for special objects. There are at present 170 qualified medical missionaries in active service at home and abroad, whereas before 1871 only thirty were in the field. Can London say that she has done her share in this useful work? The noble and devoted Robert Moffat said that a medical missionary was a missionary and a half, or rather a double missionary. Many other generous testimonies from clerical colleagues to the value of medical pioneering in missionary work are given in these pages, which leave no doubt that, as the early history of Christianity was associated with great gifts of healing, so its extension is to be. We earnestly commend this book to the sympathy and attention of our readers.

Handbook for the Instruction of Attendants on the Insane. Prepared by a Sub-committee of the Medico-Psychological Association. London: Baillière, Tindall, and Cox. 1885.

Lectures on the Care and Treatment of the Insane, for the Instruction of Attendants and Nurses. By W. C. WILLIAMSON, M.D. Paramatta. Printed at Sydney. 1885.

THE intention of the short manual of sixty pages issued under the auspices of the Medico-Psychological Association is of the most commendable kind, there being no greater desideratum in the treatment of insanity than well-trained and instructed attendants. The directions given for nursing and general duties are well compiled; while the information in regard to the forms of mental disorder and the directions as to the management of the different mental states are also distinctly good. The epitome of anatomy and physiology, however, with which the handbook begins, is of doubtful value and might confuse rather than instruct. On the whole, the handbook is a decided advance on the usual manuals of rules and instructions in use in asylums.

Dr. Williamson's Lectures are deficient in the amount of instruction and direction given in reference to the special management of the insane, and are redundant in information in regard to the treatment of diseases. They are, however, satisfactory in bearing testimony to the recognition in Australia of the importance of training attendants.

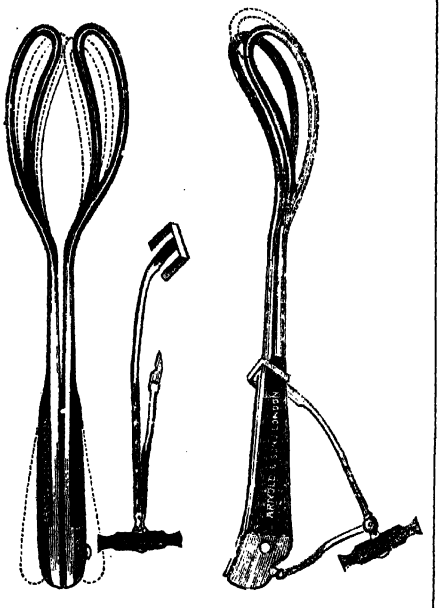


AN International Congress of Hydrology and Climatology will be held at Biarritz from Oct. 1st to 8th. The work of the Congress will be divided into, and papers read on, the three following sections:—Scientific hydrology, medical hydrology, and climatology. Numerous excursions have been arranged, and we are assured that a hospitable reception awaits those who attend the meeting from its promoters.

TWO deaths from eating poisonous fungi in mistake for mushrooms have just occurred at Nottingham.

New Inventions.

A NEW AND IMPROVED CLAMP FOR HÆMORRHOIDS.



THE method of crushing piles, instead of dealing with them by ligature, was an important advance in rectal surgery, and the question of the best form of clamp has followed naturally upon the adoption of the operation. The use of existing instruments during a term of years led the inventor of the present clamp to consider, with considerable interest, how far the necessities of the operation were met by the crushers at present existing, and how their shortcomings might be rectified. To many surgeons Benham's clamp has commended itself by its power, but at best it has always appeared a heavy and unwieldy weapon. To others Allingham's fenestrated crusher has been acceptable, as a distinct improvement, by its greater handiness, as compared with the former; but admirable as this undoubtedly is, there are certain points to which exception may fairly be taken—notably, that the pile seized by the tenaculum has to be drawn through the fenestrum, and that as by necessity a considerable amount of tissue is brought into the area of the crushing bars, a larger surface than is strictly necessary is crushed, and a correspondingly large wound remains to be healed. In the hope of overcoming these objections this new clamp was designed, and after much thought and consideration the principle of the familiar "spanner" or "screw-hammer" was adopted as a model. The instrument has been admirably manufactured by Messrs. Maw, Son, and Thompson, of Aldersgate-street, and whatever fault is found with it by expert rectal surgeons or the practitioner at large must be laid to the charge of the inventor, and not to that of the manufacturers. The accompanying woodcut will convey a very excellent idea of the *modus operandi*. It will be seen that the principle of the lever action has been discarded, and that the crushing power is obtained in a direct line by screw action, as in Allingham's, with this difference, that whereas in the latter the lower bar is forced upon the upper, here the upper bar is drawn down upon the lower. A slow screw has been adopted, as giving greater power to the operator. It may be contended that greater power is obtained with the older instrument, but in the opinion of the writer too much stress has been laid upon the power actually required for the complete destruction of the tissue; and, moreover, actual experiment has shown that the present instrument can be credited with the possession of a positively increased crushing power, while the results obtained have been sufficiently conclusive and successful to warrant the claim advanced for it as an "improved clamp," and as such it is confidently placed at the disposal of the profession.

CHARLES JOHN SMITH,
Selborne-[illegible]moderate. [illegible]on to the Farringdon Dispensary.

AN AXIS-TRACTION MIDWIFERY FORCEPS WITH SLIDING BLADES.

I DESIRE to invite attention to a midwifery forceps recently produced by Messrs. Arnold and Sons, of West Smithfield, embodying in a shapely fashion some suggestions of mine intended to increase the adaptability of the blades to the fœtal head, and to secure axis traction by as simple a mechanism as possible. The pelvic curve of the blades, now generally adopted, prohibits that free rotation about the long axis which with the straight forceps enables us to select the cranial meridian best suited to their application, and, in the absence of any compensatory adaptive movement, the restriction proves often a source of weakness and embarrassment. This is especially noticeable, for instance, when the head is detained above the brim in a transverse position. Here the occiput and the forehead suggest themselves as good resting-places for the blades; but, as an unfortunate rule, they are situated at very different obstetric altitudes, and the English lock peremptorily insists on symmetry. Hence, in order to get any hold on the forehead

with the one blade, its fellow has to be pushed beyond the occiput, as far indeed as the fœtal anatomy will allow, and then a very unsatisfactory grip is obtained, effected mainly by the tips of the blades, and causing proportionally severe pressure marks. These I have several times observed to be located, one between the orbits and the other close upon the vertebra prominens, and, in a case of spinal disease involving that vertebra, the mother tells me her infant had been badly cut just there by the instruments used to accomplish delivery, as well as on the upper part of the forehead, where a large scar is visible. With a sliding movement such faulty dispositions of the blades as the above imply seemed improbable, and my experience of the new forceps accords with this expectation; for I have found them to be secure in their grasp and gentle in their dealing with the integuments. The illustrations afford a good idea of the instrument; but on an exact side view the blades do not appear to join the stems at an angle, and the handles are seen to be slightly recurved at the lock. Longitudinal somewhat circular sliding movement is provided[illegible]lled by two pins in the one by [illegible]s in the other. The proximal pin, working as a screw, can be varied in length, and determines the span of the blades. Locking is effected by a separate piece, and the axis-tractor easily applied after the introduction of the blades, which it unites rigidly together under the simple operation of tractive force applied to its handle, whilst between the pains it can be unshipped at will by a slight push. Owing to the length of the stems the lock is always quite outside the vulva. There is no screwing together of the handles, and the head can be relieved of pressure by a turn or two of the proximal pin or by undoing the lock. One hand on the handle of the tractor commands the whole instrument. Regarding axis-traction, I would only remark that my experience convinces me its advantages have not been over-rated. The saving in muscular effort far exceeds my anticipations, and the probability of misdirecting the power seems very much lessened.

W. MC LAURIN, M.B., C.M. Glas.

Richmond-road, Barnsbury, N., Aug. 1886.

THE BRACHIONIGRAPH.

THIS instrument is a patented invention designed with a view to render the art of writing possible in the absence or uselessness of the hand. It can be thus adopted in cases of writer's cramp, certain cases of paralysis of the digits, and in loss of the distal extremity of the upper limb. The instrument is of sufficiently simple construction. It consists of a long light strip of iron, curved so as to be easily adapted to the ulnar border of the forearm. This splint is sewn into a casing of supple leather material, which is also shaped so as to form a kind of gauntlet or sleeve to the forearm. The gauntlet is fastened to the forearm by an ingenious arrangement of a screw hooks and studs, allowing of a very adjustable degree of pressure. The bar or splint carries at the distal end a mechanism with a universal joint, by means of which a pen may be held in any desired position. With this instrument the act of writing is performed by the muscles of the arm and shoulder, whilst those of the digits and thumb are thrown completely out of use. It is very easy to acquire the necessary dexterity for legible "handwriting." The invention is the work of Mr. W. Macgill, of the Academy, Fraserburgh, N.B.

DR. WRIGHT'S HYGIENIC DOWN BED QUILT.

THE advantages and usefulness of ventilating coverlets may now be said to be fully proved. The methods by which the quilt is rendered pervious to the exhalations of the human body during sleep are, however, somewhat varied. That adopted in Dr. Wright's quilt, in which lace insertions are introduced from the sides and the four corners to the centre, whilst contributing to beauty of appearance, is also very efficient in securing free ventilation, which has been the chief object aimed at by the designer of this handsome coverlet. It is manufactured by Mr. R. Thornton, Goldsmith-street, E.C.

IMMISCH'S PATENT METALLIC THERMOMETER.

THIS excellent little invention has received an additional improvement in the form of a screw mechanism attached to the ring of the watch. By its means the ring can be removed and its place taken by a long stem of whalebone. The object is to make the thermometer available for taking the temperature of the body in the vagina and rectum; it also, in our opinion, renders the registration of the mouth temperature more easy of attainment. The instrument may be obtained of all scientific instrument makers and opticians.

THE fourteenth annual meeting of the American Public Health Association will be held at Toronto, Canada, from Oct. 4th to 8th.

THE BRITISH MEDICAL ASSOCIATION.

MEETING AT BRIGHTON.

THE following is the conclusion of our report of the proceedings in the Public Medicine Section on the 6th inst.

Dr. WILLIAM SQUIRE read a paper on the Influence of Increased Means of Isolation in Checking the Prevalence of Scarlet Fever in London. Infectious diseases, like small-pox and scarlet fever, are not, said the author, checked by such general sanitary improvements as are efficacious against enteric fever and diarrhœal diseases. Improved drainage and water-supply reduced the deaths from enteric fever in England and Wales—first, from 20,000 to 15,000, and then, since 1879, to less than 8000 annually. All this time the scarlet fever mortality, except for the years 1860-61, is about 12,000 annually, with epidemic leaps, as in 1864 and 1874, to 20,000 or 30,000. In London alone the mortality from this cause (the first year of compulsory school attendance) exceeded 6000; until the last two years this has always exceeded 2000. Last year this was reduced to 700, and for the first quarter of the present year to 102, about half of the previous year, or less than one-third of that of 1884. This lowest number ever registered for London is coincident with increased means of isolation and improvement in its method. Small-pox and scarlet fever must be noted in this connexion; they, with typhus, are the only true infectious diseases which have been dealt with on a large scale by isolation, and the means devised for the first have been adapted to the others, with such modifications as their different natures required. Typhus was soon arrested, but the other two, besides special wards and hospitals, required convalescent establishments. It is well known how rapidly and completely the last small-pox epidemic collapsed after the convalescent camp at Darenth was in full action. In dealing with small-pox, hospitals alone might have sufficed, for the first action of the London Asylums Board hospitals was to reduce the small-pox mortality in London from 9698 for the two years 1871-72 to 113 for 1873, and to 103 only for the two years 1874-75, lower figures than had ever till now been known for small-pox in London. Litigation and ill-advised restrictions had so far interfered with these means, that when, in 1876, small-pox reappeared in the north and north-east of London, there was no hospital of the Board open except the one at Stockwell. Next year hospitals at Fulham and Deptford were constructed, to aid the one at Homerton. At Fulham 320 acute cases were received in six months; of these 138 came from Kensington, 80 from Chelsea, and 39 from the Fulham district. Small-pox, which was extending in the neighbourhood before the hospital was open, had subsided in July, when it was in full use. Altogether 11,000 small-pox patients were treated in these hospitals, but the mortality showed that not half the severe cases had been isolated. In 1881 the transference of convalescents to Darenth much relieved the London hospitals. In 1884 and 1885 the increased accommodation and the use of two hospital ships at Dartford, with steam launches fitted as ambulances, had reduced the mortality to *nil*. From February, 1884, to the end of 1885, upwards of 11,000 sick and convalescent were thus safely sent down the river by these steam ambulances. Altogether 10,718 cases were treated in the hospital ships. Last year there were 5644 admissions; 4069 direct from their homes, 1575 from other hospitals. The deaths were 444, being a mortality of 7·6 per cent. Dr. Bird Wood, in his report (page 7), says the severe cases are treated together. "On the *Atlas* 30 acute cases have been in bed at the same time on one side of the deck. On the *Castalia*, 20 beds in No. 3 ward and 14 in No. 8 have been occupied by confluent cases for several weeks. Neither patients nor staff were injuriously affected." The extensive arrangements made by the Asylums Board for convalescents from small-pox enabled more and more space at their different London hospitals to be set aside for fever cases, and especially for scarlet fever; much may be done by an intelligent isolation at home of scarlet fever patients where the nature of the dwelling makes it possible. One reason why diphtheria has gone on increasing in London, while scarlet fever has been reduced to the lesser mortality of the two, is that our means for isolation of the sick hardly touch diphtheria any more than they do measles or whooping-cough; the increase of those diseases is chiefly kept up by schools. Even if it be premature to attribute the great subsidence of two epidemics exclusively to isolation, it is well to insist on the coincidence; for the period for epidemic increase of both is at hand, and neither Winchmore Hill nor Darenth are completed. Instead of deferring those works till the new increase appears, we ought to be beforehand with the first evidence of such increase. In the case of scarlet fever, too, isolation is our only defence; no personal immunity, as by vaccination, can be acquired.

On the question of the Duration of Infectiousness in Scarlatina, Small-pox, Measles, Mumps, and Diphtheria, Mr. VACHER (Birkenhead) said it seemed to him that a very great change had taken place in professional opinion in respect of the time when infectiousness commences or may commence. It used to be held and taught that the diseases under consideration, especially scarlatina and small-pox, were but slightly infectious during the early stages, and that, at all events if the patient were isolated as soon as the disease could be diagnosed, no risk would be incurred. Then as evidence accumulated that subjects who showed no rash or sore-throat occasionally communicated disease days before they were suspected of having it, this opinion became untenable. In particular, there was abundant testimony that measles was very infectious for fully four days before the appearance of the eruption. Now current opinion declared that possible infectiousness commenced with the manifestation of the earliest physical sign of disease. Quite lately Mr. Vacher was led to question the soundness of this doctrine as to the beginning of infectiousness. It is doubtless within the truth to say that infectiousness is not very active as long as the disease is wholly latent. Still, approaching the question from this direction, it appeared to him that the only defensible position to occupy is to admit the possibility of infection from any infected subject—that is, during the whole latent period. For the first twenty-four hours after inception, it may be, the risk of infection is almost infinitesimal, but it probably increases hour by hour, and Mr. Vacher sees no reason to infer that it is much less just before pyrexia than just after, or much less on the eve of the eruption than when the eruption is fully out. The result of accepting the propositions put forward would be that practitioners and officers of health would advise and take steps for the isolation of all subjects exposed to infection, as far as practicable. It may be said that this has been done already in districts where so-called "houses of detention" have been provided. This is so, but the avowed object has always been to take time by the forelock and be prepared for a possible danger in the future, and not under the apprehension that the subjects separated so long as they appear well could be themselves infectious. The question of the duration of infectiousness resolved itself into two distinct inquiries—(1) When does it begin? and (2) When does it end? It remained to discuss question No. 2. There was little difference of opinion as to the [illegible] which this question was to be moderate.

TABLE SHOWING DURATION OF INFECTIOUSNESS IN SCARLATINA, SMALL-POX, MEASLES, MUMPS, AND DIPHTHERIA.

	Scarlatina.	Small-pox.	Measles.	Mumps.	Diphtheria.
Time from inception to first precursory sign	3 days	12 days	10 days	14 days	3 days
Time from inception to commencement of eruption, of glandular swelling in mumps, and sore-throat in diphtheria	4 days	14 days	14 days	18 days	5 days
Time from inception till infectiousness ceased	5 weeks mean, 10 weeks max.	5 or 6 wks. mean, 15 or 16 wks. max.	4 weeks mean, 8 weeks max.	5½ weeks maximum	3½ weeks mean

answered. Infectiousness terminated as soon as all infectious matter was eliminated. The practitioner sought to encourage this elimination, to sterilise the infectious matter eliminated, and to state when the process was completed. Mr. Vacher then proceeded to consider the length of time taken to eliminate all infectious matter in the case of each of the five diseases named. His experience of upwards of ten years as physician to the Birkenhead Fever Hospital and elsewhere enabled him proximately to set a limit to this time. A summary of his conclusions as regards the five diseases is given in tabular form above. Mr. Vacher remarked, in conclusion, that while it was possible, as regards cases isolated and treated, to set a limit to their infectiousness, there was almost no limit to the infectiousness of cases neglected and left at large. He had known of patients suffering from small-pox, scarlatina, and measles wandering about and going from lodging to lodging, sowing infectious particles in a town as a man sows wheat in a field; and he was assured that all the sweeping and scavenging, and "vague chemical libations and powderings," which urban authorities put faith in, would not prevent the crop from coming up.

MR. PHILIP BOOBBYER (medical officer of health, Basford Rural Sanitary Authority, South Notts) read a paper on Scarlet Fever in relation to the Disturbance of Impure Subsoil and the Construction of Sewers. The Greasley division of the Basford Rural Sanitary District, South Notts, comprises an area of 23,230 acres, with a population of about 31,000, which is divided between several small townships, such as Kimberley and Eastwood, many colliery and agricultural hamlets, and scattered rural dwellings. Artificial drainage is exceptional, the soil and subsoil mostly porous, and the surface frequently much polluted with accumulated organic refuse. Scarlet fever, during the past five years at least, has been more or less endemic at its northern and southern extremities. At the beginning of December, 1884, a few scattered cases only existed among the rural population of the north; but after this date the fever spread, though slowly and unequally, along the eastern slope of the Earwash Valley. In the following February, during this slow extension, two hamlets widely separated from one another, and from direct sources of infection, were almost simultaneously invaded to a very general extent, whole families being attacked at once. In both these villages considerable surface- and sub-soil disturbance had taken place, with a wide distribution of long-accumulated midden contents as manure. Many cases of enteric fever and diarrhœa, and much health depression, existed contemporaneously. There was no diphtheria, however, and no tendency to epidemic extension of any disease but scarlet fever. The type of the latter, though distinct, was mild, and the death-rate exceptionally low. This epidemic rapidly declined during March. Towards the end of April, scarlet fever reappeared in the south—at the outskirts of the Kimberley township, where excavations had been commenced for a new sewage system. The fever spread here in a remarkably general way, following the course of the excavations in all directions. The place had been visited by it in February to a slight extent, but this renewed epidemic filled up the gaps left by the previous visitation, and in many cases, again, affected whole families at once. Its generalness was especially marked in an outlying part of the township, chiefly inhabited by colliers, which up to this time had been altogether undrained. The epidemic continued during the progress of the sewage works, its final disappearance being almost coincident with their completion. The mortality here, as elsewhere, was extremely low, not exceeding 3 or 4 per cent. of those attacked. Septic glandular symptoms were common, the submaxillary glands suppurating and even discharging pus from their ducts in many cases; such symptoms, however, were not usually of very serious augury. Several cases of late and deferred desquamation were observed, and many instances of second attack in the same individual reliably attested.

NEW HOSPITAL AT HASTINGS.—The memorial stone of the new Hastings, St. Leonards, and East Sussex Hospital, which is being erected at White Rock, opposite the pier, was laid on the 24th inst., by Lord Brassey of Bulkeley. The structure is estimated to cost £20,000, provides for about 70 beds, and will probably be finished towards the end of next spring. At the close of the ceremony contributions amounting to over £500 were handed in.

THE MEDICAL ACT OF 1886.

To the Editor of THE LANCET.

SIR,—In reply to "Nemo" in your issue of the 14th inst., I might venture to add "Mortalium omnibus horis sapit"; but "audi alteram partem." The Act of 1886 is retrospective as to recognition of diplomas otherwise than British. It is ridiculous to imagine anything so absurd as expecting American M.D.'s settling here to practise under such unfavourable conditions as the above Act will place them in in the future. Rather ought we to look at home first, and by our united efforts endeavour to prevent the hosts of unqualified practitioners from treading on our toes. To quote the *Eastern Argus* of the 14th inst., where a juryman at an inquest remarks that "one of the most menial servants, a boot-cleaner or dish-washer, might be termed a doctor's assistant, and sent out to attend patients." That this is practically the case I could easily confirm if called upon. But as regards the American Faculty, I must protest against the insinuations of your correspondent, as they are calculated grossly to mislead professional opinion. The subject is so well worn that it would appear superfluous to reiterate facts—viz., that it is not possible to obtain a diploma from any recognised school of medicine in America without having studied three years and passed the required examination before the Faculty. As a pupil of the late Dr. Austin Flint, I can safely say that a more eminent body of men (of which he was the Professor of Medicine) did not exist in my time. But contrast this with the Brussels M.D.: a man simply goes to that town, and after passing an examination is instantly dubbed M.D. Which is the most reliable qualification? It has been very much the custom amongst English professional men to look down upon their American *confrères*, without due consideration being given whence they emanate. Because black sheep exist, is everyone bound to be a negro? If so, how can you admit Oliver Wendell Holmes, John S. Billings, and Fordyce Barker to come amongst you? Your diplomas are respected in America; why not leave dirty water alone, especially as so much exists in their own besom. As to "Nemo's" remarks about *time* I think enough has been said; if it comes to *money*—I might say still more; for it certainly cost me a considerable sum before I obtained my M.D. degree.

I am, Sir, yours faithfully,

August 16th, 1886. AN M.D. OF NEW YORK.

DURATION OF INFECTIOUSNESS OF SCARLET FEVER, SMALL-POX, MEASLES, MUMPS, AND DIPHTHERIA.

To the Editor of THE LANCET.

SIR,—In your report of the "Brighton" discussion upon the above subject a list of infectious periods is given and attributed to Dr. Hope. May I correct this account by stating that I began the discussion and gave the table alluded to. Without giving all the details of cases upon which my record is based, but which I reserve for future publication, I submitted the following periods as characterising the infectious stages of the several diseases:—Measles from the second day of the disease, for three weeks; small-pox from the first day, for four weeks; scarlet fever from the fourth day, for seven weeks; mumps from the second day, for three weeks; diphtheria from the first day, for three weeks. Intimately associated with these are the so-called incubation periods. From some exceptional opportunities of observation I have found the following intervals to occur between the definite exposure of the patient to infection and the first symptoms:—Whooping-cough, fourteen days; mumps, eighteen days; measles, ten days; small-pox, twelve days; scarlet fever, three days; diphtheria, fourteen days. The statement about the last-mentioned disease is, I believe, new, as no observations seem to be recorded and nearly all authorities are completely silent. One distinctly says "the incubation period is unknown." From four cases I had reliable opportunities of fixing the period of fourteen days, and in two or three other cases almost exactly the same time elapsed, but there was some difficulty in fixing the exact date of invasion. I am Sir, yours truly,

Haslemere, Aug. 25th, 1886. T. FREDERICK PEARSE, M.D.

THE LANCET.

LONDON: SATURDAY, AUGUST 28, 1886.

THE climatic treatment of disease having thoroughly established itself as one of the recognised resources of therapeutics, the multiplication of health-resorts has gone on apace, favoured by the spirit of an age of travel and geographical discovery. Our ancestors, when in search of health, sought our own southern coasts or the South of France, while Madeira or Egypt marked their furthest flights. Now every zone is laid under contribution, and the most inaccessible regions are freely recommended as affording those climatic conditions requisite for the cure which has baulked the efforts of medical skill. The claims of many of these bran-new and highly-vaunted sanatoria must be pronounced to rest upon the most unsubstantial foundations. Indiscriminate eulogies and unqualified assertions of extraordinary salubrity, penned frequently by persons whose impartiality is not above suspicion, and too often unsupported by a fragment of definite scientific evidence, cannot seriously affect the views or the practice of the profession. It would conduce to the advancement of a valuable branch of our art, and prevent many abortive volumes from ever seeing the light, if it were clearly recognised that any claim on behalf of a new sanatorium must be based upon a long series of careful meteorological records and some modicum at least of detailed clinical evidence. Amidst the excusable bewilderment engendered by the conflicting claims of a multitude of foreign sanatoria, it may not be inopportune to consider how far our own health-resorts meet the increasingly clear indications for the successful climatic treatment of disease.

The health-resorts of Great Britain and Ireland possess at least certain indisputable *primâ facie* advantages. Facility of access, the avoidance of the worry and expense of long journeys, proximity of the invalid to home and friends, superior accommodation and hygiene, and a better food-supply,—these are among the very important advantages which can be claimed for the home as compared with the foreign sanatoria. As against these must be set the inevitable drawbacks of a cool and humid climate, the long, dreary, sunless winter, the interference with out-door exercise and amusement, and the unfavourable influence upon many diseases of the combination of cold and damp. Let us consider how these opposing conditions affect the case of the three chief classes of sufferers who seek climatic treatment—viz., first, the large class of neurotic and dyspeptic patients; secondly, the gouty and rheumatic; and, thirdly, consumptives.

The first class is a very wide one, and includes those who, through over-work, vicious excess, or inherited tendency, suffer from debility of the nervous and nutritive functions. In many such cases climatic treatment is indispensable, but it is not possible to define precisely the meteorological conditions suitable to a group the members of which present many points of diversity. It may, however, be confidently asserted that for the treatment of such conditions it is only exceptionally necessary to go beyond the limits of these islands. If a marine locality be thought desirable, we have upon our extensive coast-line an unparalleled variety of watering-places, representing the most diverse types of local condition and therapeutic influence. Speaking broadly, the health-resorts of the east coasts are stimulating, those of the west, and especially those of the south-west, sedative; while those upon the south-eastern littoral hold an intermediate position. Ramsgate, Cromer, Redcar, and Whitby may be taken as representatives of the first class; Bournemouth, Torquay, Penzance, and Ilfracombe of the second; while Eastbourne, Folkestone, and Hastings are types of the third class. The selection must depend upon the physician's appreciation of the finer points in his patient's case, but it is far from being a matter of indifference, and the indiscriminate recommendation of sea air without regard to the diverse conditions presented by different watering-places is an inexcusable error, which is, we trust, becoming increasingly rare. If the dyspeptic or neurotic sufferer be intolerant of marine influence—a not uncommon phenomenon,—we have a sufficient variety of suitable inland resorts from which to make a selection. If we desire a mild and sheltered locality, for instance, Tunbridge Wells affords these indications; if a more tonic climate be requisite, such resorts as Malvern, with its charming scenery, delightful air, and admirable water-supply, are indicated; while Buxton, Ilkley, Harrogate, Weymouth, and Crieff may be mentioned as examples of health-resorts of the bracing and stimulant type.

For the treatment of the second class of invalids—viz., the gouty and rheumatic—the presence of mineral springs is important, and Nature has not been niggardly in her gifts to us of this kind. Bath, Cheltenham, Droitwich, Matlock, Leamington, Woodhall, and Harrogate in England, Moffat and Strathpeffer in Scotland, and Ballynahinch and Lisdoonvarna in Ireland, are a few of the many natural mineral springs in these islands. Yet the popularity of this class of our health-resorts seems unquestionably on the wane—not from any change of medical opinion, but as a consequence of the fluctuations of fashion and the increasing attractiveness of competing foreign resorts. Bath has not quite recovered its last century celebrity; Cheltenham is now noted less for its waters than for its educational establishments; and a similar tale of decadence might be told of Leamington; while thousands of Englishmen hurry annually abroad to drink at Aix-la-Chapelle or Carlsbad the waters which a former generation were content to take at home. It is certain that the great popularity of the foreign spas is not due solely or chiefly to the superiority of their waters, but rather to the perfection of their methods of balneo-therapy, to the influence of fashion, and the skill with which the foreigner caters for the amusement of his English patrons. If the stream of fashion could be diverted to our own mineral springs, and if the rigorous rules of diet and hygiene which are cheerfully acquiesced in abroad were similarly enforced at home, there can be little doubt that the results attained with us would rival those of the most noted French or German establishments.

The third class of patients seeking climatic treatment is in some respects the most important of all. More is expected from a judicious change of climate in the case of moderate

of phthisis than in any other disease, and no question can be more important than to determine how far our own islands afford sanatoria suitable for combating the national scourge. Our consideration may be limited to those health-resorts which are suitable for the winter season, as consumptives usually elect to spend the summer amid their own circle of friends, without regard to climatic conditions. The southern coast has long claimed almost a monopoly of attention in the treatment of phthisis, and the merits and pretensions of Hastings, Ventnor, Torquay, and Bournemouth are familiar to the profession. That the results attained at these resorts frequently rival those gained at Cannes, Nice, and Mentone is unquestionable, and the indiscriminate ordering abroad of every consumptive is much to be deprecated. It must be admitted, however, that the great variability of the English seasons is an embarrassing factor in our calculations, and that there are some winters in which the constant prevalence of snow, rain, or cold winds limits outdoor exercise and amusement to a degree that cannot fail to be prejudicial. Ventnor and Torquay are the mildest of the English resorts, but prove somewhat too relaxing for some constitutions. Bournemouth sets much store upon its pine woods. In cases of stationary phthisis with retention of fair constitutional vigour, the results obtained at the more bracing resorts, such as Hastings or St. Leonards, are often very satisfactory. Less known, but not less noteworthy, are the southern Irish resorts. Queenstown possesses one of the best winter climates in these islands; and Glengarriff, at the head of the charming Bantry Bay, where the arbutus flourishes throughout the year, combines good hotel accommodation and delightful scenery with a singularly mild and genial winter climate.

The question has frequently been raised whether we can obtain within the limits of these islands any approximation to those conditions which have rendered the high altitude treatment of phthisis so famous at Davos and elsewhere. To this question the answer must be in the negative. The influence of rarefaction of the air upon phthisis appears to be slight under 1500 or 2000 feet, and we have no sanatorium at this elevation. Further, our winter presents meteorological conditions the most diametrically opposed to the brilliant sunshine and intense dryness to which the climate of the upper Alps owes no small portion of its efficacy.

DISEASES of the uterine appendages have been brought during the last ten years into great prominence—a prominence which has not yet been shown to be deserved. This state of things has been brought about, not by any careful study of the physiology of the organs involved or of the etiology and pathology of the diseases to which they are subject, but by the frequency with which women have been made the subject of the operation of spaying—in fact, by the clumsy method of "setting the cart before the horse." The great frequency with which the uterine appendages are the seat of disease demanding their removal has often been asserted, but on evidence which has quite failed to carry conviction to the mind of the profession in this country; while the beneficial results of the operation of spaying in such cases, although asserted and reasserted, have not as yet received such evidence in t[illegible] place the operation in the position in which those who frequently have recourse to it would fain see it. In the June number of the *American Journal of Obstetrics* is published a paper by Dr. HENRY C. COE, pathologist and surgeon to outpatients to the Woman's Hospital, New York, entitled, "Is Disease of the Uterine Appendages as frequent as it has been represented?" Dr. COE, from his official position as pathologist to the Woman's Hospital, has had a good field for observation. His experience, however, is not limited to the cases in that hospital, but many uterine appendages which had been removed on the supposition that they were diseased were sent to him for examination. The results of his investigations, and the conclusions he derives from them, are contained in his paper, and these conclusions we recommend heartily to the profession in this country as well as elsewhere. The ovary in health passes through a series of states which there is no reason to doubt are often described by operators as states of disease. In one stage it is small and ribbon-like; in another it is plump, full, with a smooth surface; in another it presents several vesicles on its surface; in a fourth it is enlarged, congested, œdematous, and swollen; in another, again, it is small, hard, firm, devoid of follicles, its surface fissured and thickened, cirrhotic. All these conditions are natural and healthy, and yet almost all of them have been made reasons for the operation of spaying. Dr. COE says, "Agnosticism in regard to ovarian and tubal pathology is viewed with small favour at the present day. A peculiar feature in the growth (if it really is growth) of abdominal surgery among us is that it owes its impetus to the surgeons rather than to the pathologists.....The gynæcologist will remove the ovaries and tubes, and will afterwards call upon the pathologist to justify the wisdom of the operation, which, to tell the truth, is often extremely difficult to do."

The criteria of disease of the ovary employed by the laparotomist, "who judges entirely by outward appearances," are "a considerable increase (or decrease) in the size of the ovary, thickening of the cortex and stroma, the presence of several cysts on its exterior—these are the common results which are alleged at the operation-table in justification of its removal." Dr. COE discusses these criteria, and shows that all the conditions mentioned are compatible with perfect health of the ovary. "But," adds the author, "of all the reasons urged in justification of oöphorectomy, that of cystic degeneration is the one most frequently heard. Time and again have I seen passed around in societies ovaries on the surface of which were three or four vesicles not larger than small peas, and rarely have I heard this diagnosis of 'cystic degeneration' called in question. ..... Now, without venturing to dwell upon such a disputed point, I would only call attention to the fact that if all these so-called cystic ovaries are to be viewed with suspicion as the forerunners of possible cystomata, there are few women who can be regarded as positively out of danger." This, however, is not all. Cystic degeneration, cirrhosis, &c., of the ovaries are not the only conditions which demand their removal. Dr. COE proceeds: "HEGAR makes the following peculiar assertion, 'There are unquestionably changes within the ovary, invisible, and not at all recognisable clinically, which may however, occasion severe

and protracted symptoms of disease, so that castration may be indicated even when anatomical changes are not demonstrable.' Comment is unnecessary. Such doctrine may be reassuring to the indiscriminate operator, but to the more conservative it will savour not a little of barbarism."

The tubes have recently acquired an importance which they have not hitherto commanded, but this importance is surgical rather than pathological or physiological. It has been long known that the tubes are subject to inflammation and its consequences, closure of their lumen, adhesions of their extremities, &c.; but now their surgical diseases are pyo-salpinx, hydro-salpinx, catarrhal salpingitis, chronic catarrh, commencing pyo-salpinx, hypertrophy, stenosis, congestion, enlargement, dilatation, œdema, &c. It should be remembered "that a healthy tube is capable of a distinct increase in size under the influence of vascular engorgement, that its blood-supply is exceedingly rich, and that its mucous lining is so folded as to present a surface of large extent compared with the size of the tube. As seen during menstruation and at the operating table, the congestion is frequently so extreme that the tubes appear of a deep purple hue. Slight hæmorrhages from the mucous membrane have been noted. When rolled between the fingers, the tubes seem to be, and actually are, larger than they are after removal from the body. If, added to this supposed abnormality, the surgeon discovers a few adhesions attaching the fimbriated end of the tube to its ovary, and some small cysts on the surface of the latter, the indication is clear—it must come out!"

Dr. Coe has never found catarrhal salpingitis except in the acute form in women who had died of acute peritonitis, consequent upon the extension of acute purulent endometritis. Atrophy of the muscular coat is less common than would be inferred from statements often made, while hypertrophy is by no means common. Dr. COE states that no small number of uterine appendages are removed in New York, both in hospital and private practice, and a large proportion of them passes through his hands: "I have found that undoubted pyo-salpinx existed in not more than one-fifth of the cases, hydro-salpinx still less frequently, while true hæmato-salpinx I believe to be extremely rare, having never seen but one undoubted example. I am profoundly sceptical regarding any diagnosis of pyo-salpinx in which a collection of pus cannot be demonstrated; you would certainly reject a diagnosis of abscess in which this element was wanting. Yet such diagnoses, acting upon no sound anatomical basis, are being constantly made."

We are heartily glad to see such good pathological work from an American gynæcologist. The mass of American gynæcological work—and it is very large—degenerates into treatment, and treatment of an operative kind, based upon nothing better than ignorance and fancy. The consequence is that operations and instruments are invented, which bear the name of the inventor, are practised or used by the unwary for a brief time, and are then cast away into forgetfulness. This unfortunately is the history of a very great part of American and English gynæcological work. The cart has been put before the horse, and both have come to grief. The paper of Dr. COE is, and will always remain, a valuable contribution to an obscure and much-abused subject; and cannot fail to be in America the beginning of a healthy scientific scepticism with regard to diseases of the uterine appendages and to spaying, which must lead to a more rational and less indiscriminate and fatal operative interference with women who suffer from but trivial diseases.

THE Arris and Gale Lectures delivered at the Royal College of Surgeons this year by Dr. L. C. WOOLDRIDGE dealt with questions of great physiological, pathological, and more general biological importance. We may say at once that the Arris and Gale lecturer endeavours to revolutionise at least two notions generally accepted in physiology. The chief revolution that he is desirous of effecting is the transformation of the liquor sanguinis from the comparative insignificance of a non-vital to the dignity of a vital fluid. His other chief notion is not put forward with such fervour, but is deserving of thoughtful attention. It is concerned with the perennial subject of spontaneous generation. But there is a certain antagonism between these two ideas. If we grant the first, the second loses whatever force it might have had; for if we allow that the blood is a vital fluid, it does not seem necessary to show that "life" may arise from it. To put this a little more perspicaciously: if the plasma of the blood be protoplasm in a state of excessive fluidity, is it at all surprising that it remains the "physical basis of life"? We confess to an intellectual sympathy with the first view of Dr. WOOLDRIDGE—that the blood-plasma has good claims to be considered as genuine protoplasm.

Let us follow the lecturer through the main arguments by which he seeks to establish his proposition. The coagulation of the blood has usually been regarded, since the important work of ALEX. SCHMIDT of Dorpat, as largely dependent on the presence of the white blood-corpuscles; this position is assailed by Dr. WOOLDRIDGE, who apparently shows that coagulation of the plasma of the blood can occur in the complete absence of the white cells of the blood. The coagulation of plasma without the participation of any cellular elements may be most advantageously studied in the form of peptone-plasma obtained by the injection of a solution of peptone into the circulation of a dog. A few minutes after the animal has been bled to death the blood does not clot, and by means of the centrifugal machine plasma can be obtained perfectly free from all formed elements. The injection of the peptone prevents the normal coagulation from taking place. A simple mechanical or chemical stimulus is all that is necessary in order to evoke coagulation in the plasma. Among the means by which the plasma can be made to coagulate are neutralisation with acetic acid or carbonic acid, dilution with water, or even salt solution, filtering through a clay cell or sometimes through filter-paper. This mechanical cause of clotting is very instructive, and may serve to explain the thrombosis that occurs in obstructed vessels, without having resort to the ordinary theory of thrombosis. A globule of mercury that completely blocks a vessel has no blood-clot around it, whilst a globule that imperfectly obstructs the circulation gives rise to a thrombus. ZAHN attributes the clotting under the latter circumstance to the white corpuscles, which are present in insufficient quantity when complete obstruction exists; but in view of the fact that mechanical moderate [illegible] of plasma suffices to induce

coagulation in the absence of all formed elements, ZAHN'S explanation is open to doubt. The power of the peptone-plasma to spontaneously coagulate is entirely lost if the fluid be cooled down to zero. But a precipitate is formed of peculiar microscopic appearance. It appears in the form of of regular round discs, three or four times smaller than red blood discs. After they have been separated some time they run together, and form small granular heaps. By a process of congregation and melting together, under the influence of a raising of the temperature of the plasma to the temperature of the room, the small discs may attain the size of red blood-corpuscles, and become biconcave in shape. It is these facts that lead Dr. WOOLDRIDGE to suggest the subject of spontaneous generation. The bodies separable from the plasma under the influence of cold are identical with the "blüt-plättchen" of BIZZOZERO. During the coagulation of the plasma a ferment is formed capable of converting solutions of fibrinogen into fibrin. There is some analogy between the case of the pancreas cell and the blood-plasma. Trypsin is formed as the result of the disintegration of the former, and fibrin ferment from the latter. The capability of forming a large amount of trypsin goes hand in hand with the presence of a large amount of "granules" in the inner zone of the pancreas cell, and the capability of forming a large amount of fibrin ferment from blood-plasma depends on the amount of a substance which appears in the form of most definite "granules." Attention is also called to the fact that fibrin ferment appears to be the post-mortem ferment of muscle, thus greatly strengthening the analogy between rigor mortis and the coagulation of the blood. Histologists have distinguished between fluid unformed (paraplasma) and granular-formed protoplasma. The latter is believed to be specially concerned in the functional activity of the cell. Chlorophyll granules are an illustration of the functional activity of "granules." Regarded as protoplasm, blood-plasma has its granular formed protoplasma and its fluid unformed paraplasma, like any other mass of protoplasm. Genetically considered, the blood is derived from the same cord of protoplasm as constitutes the vascular wall. When the blood-plasma leaves the vessel wall, it is the plasma that undergoes alteration, on which coagulation depends, and not on the formed element of the blood, on Dr. WOOLDRIDGE'S view. Again, the analogy with the pancreatic ferment is interesting. Trypsin arises as the result of the death of the pancreatic protoplasm; and just as the fibrin ferment is incapable of attacking living blood-plasma, so pancreatic ferment is incapable of attacking living pancreatic protoplasm and living intestinal protoplasm. Fibrin ferment acts on a special body—fibrinogen; it does not act on plasma, because this contains no fibrinogen. Trypsin acts on proteids; it cannot touch a protoplasmic molecule. The essential chemical process in the coagulation of the blood, according to WOOLDRIDGE, is an interchange between protoplasma and paraplasma, both of which bodies consist of proteid and lecithin. In the process of coagulation there is a lecithin transference, the protoplasma losing, the paraplasmic moiety gaining, lecithin; the result being the formation of fibrin, which is also a proteid-lecithin mixture or compound. Coagulation is, then, not an ordinary fermentation process. But coagulation may be a type of processes occurring everywhere. It may be that the chemical processes of life are of like nature with coagulation, and not of the same order as fermentation. The blood ferment is essentially a post-mortem production, the result of the final explosion of the plasma molecule. The fibrin ferment will not cause coagulation of the plasma. The injection of a large quantity of fibrin ferment into the blood does not cause thrombosis. But the injection of a certain proteid-lecithin compound, not a ferment, will cause the blood to clot from one end of the body to the other, provided that enough of the substance be injected.

If the process of coagulation is rightly regarded as typical of many processes of life, these processes, far from being catalytic, are the result of the union in definite proportions of complex proteid-lecithin compounds. Lecithin and proteid are constantly present wherever there is life. As in the case of the blood, ferments may arise as epiphenomena of the main processes. That lecithin is profoundly concerned in the formation of these ferments is certain, so far as the blood is concerned.

DR. CLOUSTON'S address on "the Relationship of Bodily and Mental Pain," delivered at the opening of the section of Psychology at Brighton, is an able and useful summary of certain of the prominent known facts in connexion with the subject of pain in its leading varieties. It may be doubted whether the author was happy in the title of his paper. To draw a distinction between *bodily* and *mental* pain is to imply that the mind is something apart from the body, which would, of course, involve a fallacy in science. There is in this mode of reasoning the need—which, indeed, Dr. CLOUSTON recognises—of hypotheticating an *ego*, whether for man or earth-worm, when we speak of "feeling" in the sense of sensation, apart from the direct and immediate impression of forms of motion causing changes of structure. The so-called "mental" pain of mind caused by seeing or hearing something painful is, of course, identical with the pain caused by simply thinking of the same something; and the function of cortex activity is absolutely as directly bodily as the function of ordinary nervous activity in any peripheral part of the body. It is, therefore, a misleading policy to think or speak of some forms of pain as "bodily" and of others as "mental." It would be better practically, if not also more accurate, to speak of ideational and sensory pain. Not that pain of an ideational character primarily induced in the cortex, even when subsequently radiated to the periphery and supposed to be located in some distant part, as in what is sometimes called imaginary pains, is not sensory. In truth, ideational pain is as truly sensory as any other form of pain; and the so-called "imaginary" pains of the genuine "hypochondriac" or "hysterical" sufferer are quite as real as the pains excited by cutting or bruising. In short, the nature of pain is not determined or even affected by the accident of its being induced from without or set up within the body; but if we classify those forms of pain which are induced in the cortex as *ideational*, and call those which are, so to say, projected on to the cortex from without *sensory*, we do little violence to the language of science, and we do not indirectly lend countenance to the fallacy of supposing that there must needs be an *ego* to feel, and that to that *ego* is to

be attributed the origination of mental acts, whether of volition or sensation.

Dr. CLOUSTON deals largely with MEYNERT's hypotheses, and, we think, wisely questions the accuracy of his view that pain is of "vaso-constrictor" origin. It is certainly not true that the arteries are always contracted when pain occurs, even though we may concede to MEYNERT that the stage of constriction upon which he insists may be of very short duration and yet suffice to originate pain. Meanwhile, in spite of many laborious arguments to the contrary, we must adhere to the belief that pain is invariably induced by what may be called mechanical causes. Either there is motor irritation, or pressure, or tension, or stretching, or discordant activity in one or other form. The normal as regards the physical state of the tissues affected is changed, perhaps not at the part to which pain is referred, but at the point where it has been originated. We do not doubt that the cause may be transitory while the effect is persistent, but the essential factor of pain is change in the physical state. Even when pain is induced by ideation or cortex activity, it is by change in the nerve or blood state the effect is produced.

We must confess our inability to understand what Dr. CLOUSTON means by saying, "When MEYNERT claims credit for being the first 'to insist that the processes of innervation from the hemispheres, which constitute what we term volitional acts, are nothing more than the perception or memory of the sensations of innervation,' he states a proposition which conveys no definite meaning to my mind." It seems to us clear enough that MEYNERT is simply claiming to have been the first to propound the now generally accepted doctrine that the brain can originate nothing: that, in fact, it only perceives, collates, compounds, and reflects in forms which are kaleidoscopic in their *newness*, the ideas presented to it. Congenital ideas, so-called are, in so far as they can be said to exist—and we think they must be admitted in a limited degree,—the outcome of trains of work laid by the hereditary conformation; just as though a mechanical apparatus were contrived to perform certain actions, and provided with a coiled spring which being released the contained energy would be liberated in a predetermined direction and with foreseen results. It cannot be denied that something like this occurs in the reproduction of partially educated cells in the progeny of educated parents. Without such a hypothesis, it would be impossible to account for the mutation of species or the improvement of stock, whether animal or vegetable. The law of development necessitates this hypothesis, and it is manifestly a sound one; but beyond this the cerebrum is a *tabula rasa*, and indebted for al inscribed upon it, and apparently originated by it—more correctly, reflected from it,—to the impression of externals. This is all MEYNERT means, and it is what everyone must accept and endorse.

Dr. CLOUSTON'S paper will be studied with very great interest and profit by the multitude of practitioners for its sound and useful information on the relations of neuralgia and melancholia, and for the explanation it offers of the significance, if not also of the cause, of certain forms of cephalalgia which are increasingly common, and which give the medical man much trouble on account of their obscurity, and of the difficulty of treating them successfully.

Annotations.

"Ne quid nimis."

CHOLERA IN SOUTHERN EUROPE.

THERE has, during the week ending Aug. 24th, been a decided falling off in the severity of the outbreak of cholera, both in Italy and in the Austro-Hungarian Empire. From the latter, indeed, no news has been received since the 20th, up to which date 9 more deaths had occurred at Trieste, in addition to 4 fatal attacks in a village in Carniola. In Italy the newly attacked places are only two in number—namely, Cerignola, not far from Barletta, and San Marco in Lamis, also in Southern Italy. At Barletta itself the disease is still severe, but the daily number of attacks has fallen during the week from some 40 to about 12, and the deaths from over 20 to about 6. In North-eastern Italy the number of towns and provinces from which information comes has been materially diminished, but the disease is still maintained without any break in Vicenza, Ravenna, Padua, and Verona. There is, however, a doubt whether some of the returns have reference to the provinces or the towns affected. Under any circumstances, it is a matter of congratulation to see the month of August passing by without any material increase in the epidemic. Too much importance must not, it is true, be attached to this, for some of the most severe occurrences of cholera have taken place in Europe during September, and even the later autumn months. Besides which, cholera often exhibits a tendency to decrease before some sudden increase in the area and intensity of its diffusion. But, after all, the history of the outbreak this year is, so far, rather in favour of a cessation of the epidemic of 1884-86 than of its continuance.

DEFECTS OF VISION IN CANDIDATES FOR THE PUBLIC SERVICES.

AMONG the difficulties which have arisen in connexion with the system of competitive examination for admission into almost every branch of the public service, an important one has been to decide the amount of defective vision which ought to be considered a sufficient ground of disqualification. We are not aware of the existence of any specific instructions on the subject, except as regards recruits for the army. In the case of candidates for commissions, medical officers were instructed not to reject them on account of short sight, but to report the defect, stating whether it was remediable by the use of glasses, and leaving the final decision with regard to fitness to the military authorities. There was an exception made to this in 1871, in the case of candidates for admission into the Royal Military Academy at Woolwich, who were required to "possess a range of vision which will enable them to see clearly the 2' square bull's-eye at 900 yards." The want of definite rules has been in many cases a cause of great hardship, where young men have gone through a course of instruction and have been pronounced unfit on presenting themselves for admission to the examination. Sir J. Fayrer, in his capacity as President of the Medical Board at the India Office, has done very good service in preparing "Rules regarding defects of vision which disqualify candidates for admission into the various departments of the Indian Service." These have been published under the sanction of the Secretary of State for India, with an appendix containing the information given in Sir T. Longmore's Optical Manual as to the range of vision necessary to qualify a candidate for admission into the Royal Navy, British Army, and Civil Service. We trust the authorities of the Army, Navy, and Civil Service will follow the example thus set them, and publish an authorised code of instructions for the guidance of examining medical officers, and

for the information of parents and tutors of intending candidates. In the meantime these cannot do better than procure Sir J. Fayrer's little work, and be guided by the clear instructions which it contains regarding visual defects and the mode of testing them.

MEDICAL FEES.

WRITING on this subject in the columns of the *St. James's Gazette*, "F.R.C.S." arrives at the conclusion that, looking at the fees obtainable for consultation at great distances from home, "nothing was ever so lucrative as the railway journeys of the present day." The process by which this result is reached is the following, in the correspondent's own words: "What was the state of things formerly, which I recollect? Between 11 and 12 o'clock in the morning you received a letter (unpaid) from Brighton calling you to see a patient. If you went directly upon receipt of the letter, you sacrificed a whole day's fees in London, and had to spend twelve hours at least in a post-chaise before you got home. The fee was fifty guineas. The expenses of the journey: posting £5 (if four horses, £10), with the loss and tear consequent upon 100 miles of post-chaise travelling; expenses at Brighton, £2; loss of one day's patients, £21 10s.; total, £28 10s.—leaving a balance of £24. Now a practitioner receives at 8 o'clock a paid telegram asking for his attendance; he sees all his day's patients, leaves London at 5 o'clock, sees his patient at 6.30, and, if he likes to return home the same day, is back by 10.30. Should he sleep at Brighton, he is at home in time in the morning to see all his patients for the day, at a cost of, travelling and expenses at Brighton, £1 10s. The fee is now £31 10s., leaving a gain of £30, with only a total of railway journeys of two hours and a half, with no loss of patients." "F.R.C.S." can have very little practice at home, or he must have been very much worried with long journeys in the past, and therefore feels the present state of matters to be comparatively a subject for complacency. Has he, however, forgotten the great difference which exists between the condition of things years ago and now? At the time of which he speaks everything went slower than it does now. The £24 balance left, after calculating expenses and loss, had a purchasing power quite equal to, if not in excess of, the £30 gained now; and even if the £21 10s. for patients be saved to the practitioner, the net value of his receipts on the average day's work is not so great as it used to be. Consultations at long distances occur much less frequently than in olden times, and they more seriously derange the routine business of the consultee. In short, for one fortune made in practice in the present day, there were probably three gained in the days to which the recollections of "F.R.C.S." carry him back.

THE VIRUS OF GLANDERS.

A VALUABLE communication has been made by M. Chauveau to the Académie des Sciences on the resistance of the virus of glanders to the destructive agency of atmospheric air and heat, the investigations having been carried out by M. Cadéac and Malet. The authors endeavoured at first to discover the conditions that preserve and those that destroy the virus under ordinary circumstances. They have ascertained how long the virulence persists (1) in the humours dried more or less rapidly, and in the diseased lung left to the action of the atmosphere at different seasons of the year; (2) in humours placed in an atmosphere saturated with moisture at the ordinary temperature of the atmosphere; (3) in humours diffused through water. The resistance of the virus to desiccation varies with the rate of desiccation, with the temperature of the medium, and with its humidity. In the laboratory it was found that the virulence lasts two days, no matter what the season, if the virus be exposed in thin layers in watch-glasses. In the external atmosphere, however, the virulence may be harmless on the third day or persist till the ninth; the former happens mostly in the summer or end of spring; the latter in the month of December. Meteorological observations show that a high temperature prevails and a dry state of the atmosphere in the former case, whereas in the latter the temperature is low and the air moist. Thorough desiccation of the virus means its destruction; the active virus always retains some of its moisture. If the virus be desiccated rapidly, as in a stove, at a temperature of 40°C., from one to twenty-four hours, its virulence lasts for a longer period than when desiccation takes place more slowly. Thus, a virus dried in the stove for two hours retained its activity for six days. It seems probable that this difference in the duration of the activity of the virus, when slowly and rapidly dried, is to be attributed to the more prolonged exposure to the atmospheric oxygen, rather than to any difference in the state of moisture of the environment. Fragments of farcy buds from the lungs retain virulence in the central parts as long as twenty-four days, whilst the more external layers lose theirs at rates dependent on the facility with which they become desiccated in the atmosphere. An atmosphere saturated with moisture and at ordinary temperatures preserves the virulence of the morbid humours for very long periods of time—fifteen to thirty days. Boiling the virus for two minutes in water suffices to destroy its activity, but simply pouring boiling water on the morbid material does not destroy its virulence.

DR. WENDELL HOLMES.

DR. HOLMES has unfortunately left us long before we have had such opportunities as we could have wished of expressing our welcome to him. At the last moment, as the guest of the Liverpool Philomathic Society, he spoke kindly words of affection and respect for "dear, dear England," which will be felt and appreciated everywhere. But, though gone, he is still with us as one of our most "autocratic" companions, teaching us great broad lessons of sympathy with all that is human and divine. His medical distinction may be somewhat lost in his literary fame, but we claim him, nevertheless, as one of the men whose vision has been refined and intensified by the study of medicine, and who could not have drawn some of his most effective pictures of character and experience without this study. Who but a medical man could have done justice to "the little gentleman" with his diminutive and deformed body and his disproportionate thoughts, or who else could so eloquently have vindicated the true gentleness and kindness that underlie the apparent sternness and want of feeling of the surgeon. We trust he has received a fresh stock of health, and that in the atmosphere and association of the old country, which he loves like a true American, he has found a source of fresh inspiration, the expression of which will delight the "breakfast-table" for generations yet to come.

THE TREATMENT OF TYPHOID FEVER.

THE hope of cutting short the usual course of the specific fevers still lingers in the mind of practical physicians, though it must be confessed that there does not appear to be much encouragement in store. M. Pecholier of Montpellier is of opinion that he has discovered the means of causing the premature termination of ordinary cases of typhoid fever. The agent is the familiar quinine, administered in daily doses of not less than one gramme, and this from the very first days of the illness. The drug may be aided by the employment of tepid baths if there be considerable fever, and by small doses of digitalis should the heart be specially disordered.

A CONTRIBUTION TO THE KNOWLEDGE OF THE ACTION OF URETHAN.

DR. E. BRAUN, being a sufferer from insomnia caused by heart-disease, tried the action of urethan, and contributes his experience of this drug to the *Eira*. The first evening he took a dose of two grammes, hoping confidently to fall asleep in "from ten to thirty-five minutes." In this hope he was disappointed, as, instead of sleeping, he lay in a peculiar sort of trance, conscious of all that went on round him, hearing the striking of the clocks both at the hours and half-hours, and the voices of people in the street. The following evening he again took two grammes at 11 o'clock, and, as sleep did not follow, he took another gramme in an hour's time; the same peculiar condition occurred. The third evening Dr. Braun took three grammes at a time, but without any other result. He now gave up the experiment, as he was aware that large doses were not considered advisable. About a day or half a day later he suffered from difficulty and pain in passing urine, and found on examination that there were traces of albumen. Some hours later he had fever and a severe headache. The symptoms all vanished after forty-eight hours, with the exception of the difficulty in passing urine, which lasted for several days. Dr. Braun judges, from his own experience, that immunity from after-effects with urethan is not so certain as has been stated.

FOR AND AGAINST ALCOHOL.

THE total abstinence section of the British Medical Association never fail to testify at the annual meeting. About 160 members of the Association were present at the breakfast at Brighton given by the National Temperance League. We need not say that the speakers at this meeting were not of the opinion of a recent writer in the *Revue Scientifique*—M. Fournier de Flaix. M. de Flaix maintains that the outcry against alcohol is utterly unmerited, and that all vital statistics are more favourable in nations in proportion to the use of alcohol. In France, he says, the birth-rate is lower and the death-rate higher, where the consumption of alcohol is smaller. In England, again, more alcohol is consumed than in France, and yet in France the birth-rate, the death-rate, and the statistics of crime and suicide are less favourable than in England. Comparing other nations, he reaches the same conclusions, and maintains that alcohol is an alimentary element whose consumption should depend directly on climate. Very different were the teachings of the medical abstainers at Brighton—viz., Dr. Norman Kerr, Dr. Nathan S. Davis, Professor Geikie of Toronto Medical College, Dr. Simon Fitch of Nova Scotia, Dr. Bernard O'Connor, and Dr. Ridge, Secretary to the Medical Temperance Association. Dr. O'Connor said that during his fourteen years of practice he had never prescribed alcohol for any patient. Speaking as a physician to a consumption hospital, he maintained that phthisical patients did much better without alcohol—the night perspirations and the cough were less, and the morning exhaustion was less. But the principal speaker, of course, was Dr. Nathan S. Davis—the President-elect of the approaching International Congress. Dr. Davis's disparagement and denunciation of alcohol were absolute and unconditional. It does not nourish, it does not sustain heat, it does not assist convalescence, it does not improve the pulse in fever, and it is of no virtue in nursing. It is purely evil in its effects. So far from strengthening the heart's action, it depresses it—it paralyses it. In saying so, he relied not only on his own observations, but on those of Anstie and Parkes. He maintains that alcohol is simply anæsthetic; that it does not remove evils, but makes one insensible to them; and that it arrests and retards all healthy action of the tissues, and tends to the retention and accumulation of effete materials. It is a pity that M. Fournier de Flaix and Dr. Davis did not meet at the Brighton breakfast. There is perhaps a little extremeness on either side, but of the two sides we decidedly lean to that of Dr. Davis. We entirely agree with him and other speakers in thinking that the medical prescription of alcohol should be undertaken only on the strictest grounds. M. de Flaix must remember that France now is not far, if at all, behind England in the consumption of alcohol, and that, besides, she indulges in absinthe, and he will have to explain the fact that in the temperance section of life insurance offices in England the value of life is apparently much greater than in the ordinary section, so much so that in some offices teetotal lives are taken for less premiums or receive larger bonuses. When we read the indictment of Dr. Davis against alcohol, we are tempted to ask if it is the whole truth—if alcohol has no redeeming quality. Admitting that it does infinite harm, does it do no good?—does it prevent no evil? Can the able physicians who recognise its virtues be all mistaken? The question is one for scientific and thoughtful men to discuss gravely, and medicine will not be without much authority and, let us repeat, responsibility, in its settlement.

A MINISTRY OF HEALTH.

WE have repeatedly contended that there ought to be a Department of Health in the Government of this country, and that a Minister of Health should have a seat in the Cabinet. Public Medicine is preventive, and as such it can only be effective when it forms an integral part of State policy. Surely health is not secondary to wealth; and if trade needs to be specially controlled in the interests of the State, health-promotion has a not less urgent claim to be considered a constituent part of policy. We are glad to see that the question has been reopened, and is being agitated by Mr. Hamer, a practical worker in the field of health-promotion. There are urgent matters of sanitary enterprise which call loudly for help from the Government, and which it is not only inexpedient, but a cause of weakness, to neglect. The Prime Minister who shall perceive the need and take measures to satisfy it will deserve well of his generation and serve his country.

COCAINE IN GYNÆCOLOGICAL PRACTICE.

PROFESSOR AMANN gives in the *Münchener Med. Wochenschrift* of July 20th an account of the experience he has had with cocaine in gynæcological practice during a period of about a year. He employed solutions of the hydrochlorate varying from 5 to 10 per cent. Of the strongest of these he has sometimes used altogether two grammes (one drachm), and in one case nearly double that quantity, in applications to the mucous membrane made by means of a brush every five or six minutes. In cases of hyperæsthesia and inflammation of the vulvar and vaginal mucous membrane, rendering coitus very difficult and making the passage of a small cylindrical speculum extremely painful, the condition was greatly relieved by the application of a 5 per cent. solution every day for two or three weeks. Dr. Amann tried in two cases painting the vulva with a 10 per cent. solution, in the hope of being able to remove small warts painlessly, but the attempt proved almost useless. In pruritus of the vagina, a 5 per cent. solution applied for several days by means of cotton-wool gave no permanent relief, though Hoffmann obtained good results in these cases from a 3 per cent. cocaine and vaseline solution. Urethritis, with considerable swelling of the mucous membrane, with dysuria and painful micturition, was usually greatly relieved by painting the meatus with a 10 per cent. solution every [illegible] which diminished the hyperæmia and the [illegible] moderately [illegible] part. Blumenfeld also speaks

of good results obtained by the use of a 2 per cent. solution for the purpose of facilitating the introduction of a catheter. In cases of erosion of the cervix, and cervical endometritis with contraction of the internal os, occasioning severe dysmenorrhœa, four to six applications of a 5 or 6 per cent. solution (exceptionally of a 10 per cent. one) by means of a sponge-holder or a Braun's intra-uterine syringe, with, if necessary, preliminary dilatation of the cervix, always effected a cure. In these cases, as well as in urethritis, the action of cocaine is of a vaso-contractile character. In order to show what powerful effects of this nature can be caused by cocaine, the writer goes on to give an account of an interesting case of long-neglected inversion of the uterus, the metrorrhagia, of which the patient had several attacks, at last yielding to the local application of a 10 per cent. solution. The quantity used here, however, was considerable, and the patient exhibited rather serious toxic symptoms.

THE TREATMENT OF PARONYCHIA.

DR. SELLDEN writes in the *Eira* that he has for years made a special study of this subject. The greater number of his patients have been miners, smiths, machine labourers, servants, and others whose fingers are exposed to injury. The disease commences in the subcutaneous tissue, and spreads to the periosteum. There are differences of opinion as to the varieties of this disease, some authors asserting that there are four, others that there are only two—the deep and superficial inflammation. Dr. Sellden, after a series of trials, found the following method most efficacious in the treatment of paronychia. When the patient will consent to an incision, the finger, after it has been opened, is instantly plunged in a tumblerful of hot water, which is then allowed to cool till it is nearly lukewarm. Half a teaspoonful of arnica is poured in, and a teaspoonful of the usual 10 per cent. solution of potash is added. This mixture is highly anæsthetic; the finger is held in it for from fifteen to thirty minutes, when the "bad matter" comes out. This expression is very characteristic of the phenomenon. The blood and pus exude in a thin stream about the size of a knitting needle, which forms circles in the alkaline liquid, and finally settles in a thick mass at the bottom of the glass. Fifteen minutes or half an hour after the finger is dried it is rubbed with vaseline ointment containing 10 per cent. of sulphide of potassium. The finger is then immediately enveloped in a poultice which continues warm till the next finger-bath, and thus hastens the cure. These finger-baths are taken from two to four times daily, and the wound is covered during the earlier days with sulphur ointment, and later with a boracic ointment. The finger is then bound up with a wadding compress and a bandage. Carbolic acid may be used in the finger-bath, but Dr. Sellden gives the preference to arnica, which he finds particularly useful in all sorts of injuries.

FEES FOR CERTIFYING LUNATICS.

THE Holborn Union Guardians are of opinion that a fee of two guineas is too high for the examination and certification of a lunatic. Would any member of that board contentedly place himself in a position of liability to action for false procedure at a less cost? Until the law affords due protection to medical practitioners in the discharge of their public duties, the authorities which require their service must be made to understand that it is necessary to pay for them. It is simply monstrous to expect any properly qualified medical man to devote the requisite time and attention to the study of a case of alleged lunacy, and to assume the responsibility of certifying, at a lower rate of fee than that charged. We are glad to see that [illegible] magistrates upheld the reasonable demand made.

ETIOLOGY OF GONORRHŒAL ARTHRITIS.

DR. SMIRNOFF, writing in the *Vrach* on the etiology of gonorrhœal arthritis, remarks that inflammation of the joints occurring after an attack of gonorrhœa has for a long time been looked upon as an outcome of some sort from the urethral disease, but although the genetic relation of the latter to the joint disease was generally allowed, the mode in which the metastasis takes place still remained in obscurity. It was said that the poison, which was probably of a chemical nature, found its way into the blood, and was thus distributed through the body, and so set up the joint inflammation. Since Neisser succeeded in finding gonorrhœal micro-organisms the cause of the arthritis ought to be more satisfactorily ascertained. Indeed, Petrone, Kemmerer and Prof. Afanasieff have actually demonstrated the presence of gonococci in the exudation of the joints in gonorrhœal arthritis. Taking into consideration, however, the fact that the significance of Neisser's gonococci in the etiology of gonorrhœa is not universally accepted, it cannot be considered that the arthritic inflammation is satisfactorily accounted for. An observation made by the author for the better elucidation of this matter in the Kazan Pathological Institute on the contents of a knee-joint affected with gonorrhœal arthritis is therefore of considerable interest. The case was that of a man of twenty-eight, in whom gonorrhœa showed itself on Jan. 1st, 1886. On the 5th orchitis supervened in consequence of too active exercise and on Feb. 1st the right knee became inflamed. After about a fortnight Professor Studenski drew off the fluid and washed out the joint. The quantity was about three ounces, and it was of a sero-purulent character. Thin films of it were placed on cover glasses, dried and stained with methylene blue (1 part to 33 of alcohol and 66 of water), remaining in the solution about a minute, and subsequently washed with water and re-dried. The examination was conducted by means of a Zeiss's oil immersion $\frac{1}{12}$ objective. Quantities of gonococci were seen in the preparations mingled with pus-corpuscles. Dr. Smirnoff is therefore able to confirm the previous observation of Petrone, Kemmerer, and Afanasieff as to the microbic origin of gonorrhœal arthritis.

INOCULATION OF TUBERCLE IN MAN.

SINCE the numerous facts which had been gleaned in former times on the subject of tubercle have been explained, and as it were arranged by the discovery of the bacillus, the question of the inoculability of tubercle is at once capable of comprehension and answer. The opinion that tubercle is capable of inoculation was held by many ancient writers, and Laennec himself, after a prick from a saw while performing a necropsy on a phthisical subject, thought that he witnessed an example of inoculation in a small tubercle in the skin; but twenty years afterwards the great clinician was in good health, though finally he died of phthisis. Cutaneous inoculation has been made experimentally in monkeys with perfect success, but at present facts are wanting to show that this can occur in man, however probable it may seem. In the *Archives de Physiologie* for July, Dr. Hanot, physician to the Hôpital Tenon at Paris, has collected six observations bearing on this point, which tend to show that such inoculation does take place, one case having fallen under his own observation, and the others being gleaned from recent medical literature. From these observations it would appear that tubercular matter inoculated into the skin forms at first a small papule from which a caseous kind of pus is discharged, and that this papule increases in size and extent, breaking down at the same time, so that finally an irregular ulcer is formed, which has no tendency to heal under the usual lines of treatment, and which slowly extends, so that after one or two years the

ulcer has reached a considerable size. The sides of the ulcer are formed of embryonic tissue, with giant cells containing bacilli, and sometimes the lymphatic glands are involved, sometimes not. Whether pulmonary tubercle follows the cutaneous inoculation is difficult to say. In the particular case observed by Dr. Hanot, the patient was in the third stage of phthisis, and died soon after with a tubercular ulcer on the arm of at least two years' standing; while the history of cough only dated from the last ten months, which looks very much as if the skin lesion preceded the pulmonary, and was the cause of the phthisis. The sources of inoculation were necropsies on tubercular subjects, nursing phthisical patients, handling old bones, pricking the hand with a fragment of porcelain from the broken spittoon of a phthisical patient, and in four of the cases the tubercular character of the skin lesion was verified by finding the bacilli. The subject has considerable importance, for in presence of a skin lesion of this description, the medical man must not remain inactive, for at any time there is a chance of the bacillus generalising itself and producing its fatal results in internal organs, so that complete eradication is undoubtedly the treatment called for, and eradication in such a way that the chances of aiding the migration of the microbe are minimised, which indication is best carried out by the actual cautery or Paquelin's knife.

THE CHOLERA COMMISSION.

WE understand that Messrs. Rouse and Sherrington, who, it will be remembered, were commissioned by the Royal Society to visit Italy and report on the outbreak of cholera in that country, have come to the conclusion that there are no cases of cholera in Northern Italy or in the Po valley, although the newspapers daily announce cases of the disease. The so-called cholera hospitals at Alessandria, Verona, Vicenza, and Padova have been visited, and the municipal authorities consulted, but no cases have been discovered. The laboratory with which the commission was provided has therefore proved useless. In the south of Italy, where it is impossible to work the laboratory, there are, however, cases of true cholera, but in the infected districts there is no gas or water-supply, and no hospital. The work of the commission has consequently come to an end, and we understand that a speedy return to England is contemplated.

EFFECTS OF SYPHILIS IN PREGNANCY.

DR. LOUIS HIRIGOYEN, who has published a series of articles in the *Journal de Médecine de Bordeaux* embodying the results of observations on the effect of syphilis upon the course of pregnancy, states that in the Bordeaux Maternity Charity, in which five-sixths of the cases are those of unmarried women, the syphilitic are 5 per cent. of the whole number. The author's observations go to confirm Fournier's dictum that "a syphilitic woman becoming pregnant is more likely to abort than a pregnant woman who becomes syphilitic." For example: Of eight women who had been syphilitic for more than a year, five aborted, one bore a child which died on the eighth day, and two bore living but puny children. Of nine women who contracted syphilis within the first two months, six aborted at six months and three at seven months, all of macerated children. Of three women who contracted syphilis during the third month of pregnancy, one miscarried at seven months of a macerated child, and two of a similar child at eight and eight months and a half respectively. So that in all the twelve cases where syphilis was contracted before the commencement of the fourth month miscarriage of a dead fœtus resulted, even in some cases in which anti-syphilitic treatment was diligently pursued, the only apparent effect produced being the retardation of the period of miscarriage. Syphilis occurring after the commencement of the fourth month proved less fatal, for of four cases which took place from the fourth to the sixth month, one brought forth a healthy child at eight months; the second, who was treated medicinally, went her full time, and was delivered of a healthy child; while the other two women were confined at seven and eight months respectively of puny children, which died shortly after birth. Where the infection was delayed till after the beginning of the seventh month it proved still less fatal to the children. Thus, of seven cases of this kind four terminated in the delivery of apparently healthy children, and one more might have been born alive but for maternal dystocia. The bodies of the macerated children, as well as those which died after birth, were examined, and no definite syphilitic appearances could be discovered in the osseous or other parts. Of course, treatment was adopted where the woman was seen early enough, and in all cases stringent isolation and antiseptic precautions were enforced, with the result of the avoidance of all serious accidents.

INSTRUCTION IN SCHOOLS FOR STAMMERERS.

FROM time to time we have had occasion to refer to the oral education of deaf-mutes, and we are pleased to note that this form of teaching has now become fairly established as a part of the School Board system. There is, however, yet another class of persons troubled with defective speech, though less gravely afflicted, who may claim a similar consideration. These are stammerers. Treatment and cure in their case do not call for such elaborate care as in the case of mutes. They have not lost a sense, nor is that faculty which in them is deficient—the power of co-ordinating the movements necessary for clear enunciation—entirely absent. It is rather in the condition of rusty machinery; it will work, but not smoothly. There is much hope, therefore, of a good result by training such persons. History and common experience alike bear witness that stammering is curable, and the result of an organised attempt to remedy this impediment in the school children of Brunswick has proved, it is said, that it can usually be treated at an early age with complete success. A point worth noting is that, in consequence of the comparative commonness of this fault of speech, it should not be so difficult as in the case of mutes to form within a given area classes of sufficient size to justify their separate instruction.

"A LOCUM TENENS REQUIRED—UNQUALIFIED."

IT is inevitable, and even proper, that a medical man at least once a year should leave his patients. But he ought certainly to leave them in the care of a duly qualified *locum tenens*. A correspondence has arisen in the *Sheffield Daily Telegraph* on the significance of the following advertisement, taken from the columns of our contemporary: "*Medical.*—Locum Tenens required, unqualified; out-door. Good testimonials essential. Address Medicus, *Telegraph* Office." A correspondent professes some alarm lest such an advertisement should represent a common practice, and he is followed by others who think Sheffield exceptionally given over to unqualified assistants acting under the protection of the name of a qualified practitioner. We think we may assure our readers that such a practice is not common anywhere. The writers are only too accurate in saying that if unlicensed curates or solicitors were engaged to take the place of absent members of the other professions great scandal would result, and the clerical and legal authorities would be soon brought into action, whereas the medical authorities look on such irregularities with comparative indifference. But medical men generally are too much alive to the responsibilities of practice, and, we may add, to their own interests, to leave their patients [illegible] an "qualified" hands. Unless the corresp[illegible] moderate[illegible] contemporary are much in error, the

employment of unqualified assistants in Sheffield is carried to a great extent. They are said to be put in charge of so-called "dispensaries" and of branch practices on a large scale. We should be glad to receive some contradiction of this statement.

THE EPIDEMIC OF DIPHTHERIA IN SOUTH LONDON.

AT the present time there is an unusual amount of diphtheria in districts south of the Thames. At Guy's and St. Thomas's there have been many cases admitted, especially at the former, where some of the cases have been of a very severe type. Three nurses at the former hospital have contracted the disease, and unfortunately in one case, that of Miss Blomfield, a lady pupil, the disease proved fatal. She had not entered upon the nursing duties for more than a fortnight when she commenced attendance on a patient suffering from the disease. Twenty-four hours after she had taken charge of this patient she developed diphtheria of a most malignant type, and, we regret to say, died within twenty-four hours afterwards. The nurse in attendance on her also developed the disease, but it was of much milder character and she recovered. It is difficult to account for the greater severity of the type in the fatal case; possibly the nurse had not become acclimatised to the air of a large hospital, for it is the experience of many that those much engaged in ward work are especially prone to suffer at first from those affections which attack the throat.

THE MICROBE OF CHOLERA.

THE account of his research upon the Relation of Cholera to Schizomycete Organs, by Surgeon-Major D. D. Cunningham ("Scientific Memoirs of the Medical Officers of the Army of India," Part I., Calcutta, 1885), bears out in many respects the truth of Koch's discovery. The inquiry was limited to the following points:—(1) The association of curved schizomycetes with materials of choleraic nature; (2) the presence of similar bodies in other media; (3) the effect of variations in the nature of the medium in which they are developed in the curved schizomycetes occurring in association with choleraic materials. These organisms—comma bacilli—were found by Dr. Cunningham in twenty-six out of twenty-eight cases in which the alvine evacuations were examined; they were variable in number and character. In five cases the intestinal contents were examined after death, and in all these organisms were discovered. In not one of eight cases in which the blood was examined were the bacilli found in that fluid. Cultivations in agar-agar were made from these several sources. Characteristic colonies of comma bacilli were thus produced from thirteen out of eighteen specimens of the alvine evacuations, from three out of four specimens of the intestinal contents, but in no case from the blood. Dr. Cunningham remarks truly that the failure to detect the "commas" in the cultivations (which were made under adverse conditions) does not absolutely prove their absence in the specimen employed; and believing as he does in the polymorphism of these organisms, he finds here an additional explanation of the disappearance of characteristic forms. It is an interesting fact that in a case in which the evacuation contained comma-shaped organisms, but where cultivation failed to produce colonies, the diagnosis was found to be mistaken, the case proving to be a malarial and not a choleraic one. His results are summed up in the statement that the belief in the presence of easily cultivated comma-shaped organisms in the dejecta and intestinal contents of choleraic cases is well founded. On the second line of inquiry several specimens of normal alvine evacuations were examined, and in all "comm[illegible]," but in no instance did the cultivation[illegible]clusion being either that bodies of the nature of choleraic commas are entirely absent from normal alvine evacuations, whether in actual or potential condition; or, if present, they are incapable of further development under conditions favourable to those of the choleraic organism. Dr. Cunningham also found, on examining specimens of tank water, an abundance of comma-organisms, mostly associated with and attached to the scum of Euglenæ that covered the water. His researches on this point were, however, interrupted, but in two instances he obtained characteristic cultivations. Lastly, he has studied somewhat exhaustively the changes in form which these organisms undergo in cultivation—a line of inquiry which has not hitherto been fully pursued.

THE MANUFACTURE OF QUININE BY SYNTHESIS.

A REMARKABLE discovery, by which the price of quinine may be reduced to something like 3*d.* per ounce, has been made by Mr. Cresswell Hewett. The synthetical manufacture of quinine was first suggested to Mr. Hewett in 1869 by the late Dr. Mattheson, of St. Bartholomew's Hospital, whilst giving his assistance in a course of experiments in connexion with apomorphia. Subsequently, Professor Parkes of Netley aided with his advice, and to these gentlemen, rather than to himself, Mr. Cresswell Hewett modestly explains that the process is due. The importance of this discovery is rendered greater by the fact that, while hitherto we have been depending for our quinine on the cultivation of the cinchona tree, from whose bark only about 2 per cent. of good quinine can be extracted, 98 per cent. being valueless, the drug can now be manufactured without limit by a very simple process from an article which can always be got in abundance in any part of the world. Mr. Hewett, we believe, intends to put himself in communication with the Government, who annually spend in India alone about £60,000 in the cultivation of the cinchona tree.

PUBLIC HEALTH IN SOUTH AUSTRALIA.

ACCORDING to the twelfth report of the Central Board of Health of South Australia, nearly all the local boards of health exercising jurisdiction over populous towns or districts have now attached to them medical officers of health, and a large number of townships have been personally inspected by the Board's own inspector. Amongst the more recent advances in the colony are regulations of the nature of bye-laws controlling such matters as the construction and management of cesspools, earth-closets, &c. In one respect the regulations as to the latter are in advance of anything in this country. With us, a local authority can control the construction of an earth-closet, but it can only deal with its faulty management by the cumbrous process of proving it to constitute a nuisance. In South Australia, on the contrary, the mere fact of an earth-closet not being kept constantly supplied with dry earth &c. constitutes of itself a nuisance under the Public Health Act of 1876.

RENAL TUBERCULOSIS.

M. RAYMOND DURAND FARDEL has studied the histology of renal tuberculosis, particularly with reference to the presence of the bacillus ("Contribution à l'Etude de la Tuberculose du Rein," Paris, G. Masson, 1886). The scope of his monograph is restricted to the lesions of miliary tuberculosis. It is therefore mainly of pathological interest, and it could be wished that his studies had been extended to the far more important (clinically at least) affection known under various designations as renal phthisis, scrofulous kidney, strumous pyelitis, &c. There is decidedly room for a good monograph upon this latter affection. However, so far as it goes, the *brochure* of Durand Fardel is of

importance. He has demonstrated bacilli in acute miliary tuberculosis of the kidney, within bloodvessels, glomeruli, tubules, and in the interstitial tissue, and has detected them within the glomeruli and vessels even before the appearance of the anatomical lesions of tubercle—a remarkable fact worth verification. In the early stages the bacilli are to be found preferably on the surface of the glomerular tufts, but in more advanced stages they occur in the tubercular infiltration around the glomeruli, as well as within these bodies. The presence of bacilli in the afferent arterioles is held to demonstrate the generalisation of tubercular infection by the blood stream. The paper has, therefore, a bearing upon the general subject of tuberculosis

VENOMOUS SNAKES.

A boy, aged fourteen, was admitted into St. Thomas's Hospital on Aug. 18th, suffering from the bite of a snake. It appears that he had gone to Sandown Park for the day, and whilst playing about on a bank he saw a snake moving in the grass. He seized it by the tail, thinking it to be one of the harmless kind found in many parts of the country, and the snake turned immediately and bit him on the right thumb. When the boy arrived at the hospital, seven hours later, there was no mark on the thumb to indicate the exact position of the puncture, but he pointed out a place on the dorsum just above the nail where he stated that he had been bitten. There was considerable swelling of the forearm and inner side of the arm, with swelling and much tenderness of the axillary glands. He was suffering from shock and was somewhat blanched; pulse 80, quick, and rather small. The next day there was more swelling of the arm and axillary glands, but no rise of temperature. He has since progressed favourably, though there is still some swelling of both arm and glands. It would be advisable that boys on visiting places where such snakes are known to exist should be warned of the danger of handling them, or, as in the Australian Board Schools, instructed in the difference between the harmless and venomous kinds.

INOCULATION OF HYDROPHOBIA.

WITH the virus taken from the spinal cord of a dog, which had died of hydrophobia in the Stockholm Veterinary Institute, three dogs were inoculated by Pasteur's method. To render it more certain, the meninges were chosen for the seat of operation. The dogs were carefully selected as being totally free from bites by other dogs which might have been suffering from rabies. The inoculation wounds healed after two days, and the dogs seemed quite healthy and lively. The sixteenth day after the operation two of them showed symptoms of rabies, and the third followed two days later. The first two dogs had fully developed rabies sixty days after the first symptoms had appeared. To save the third dog unnecessary suffering he was killed as soon as he developed decided symptoms of rabies.

BLOOD ENEMATA.

DR. GUTIERREZ gives an account in *El Dictamen* of a case where blood enemata proved of great service. The patient was a badly nourished woman, on whom the author had performed Hegar's operation of excision of the cervix uteri on account of hypertrophy. On the twelfth day a rigor occurred, which was followed by catarrhal pneumonia. The treatment employed relieved the pulmonary symptoms, but evening fever, partial sweats, anorexia, extreme prostration, and a highly anæmic condition persisted in spite of the employment of cod-liver oil, hypophosphites, and other remedies ordinarily prescribed. After a month had elapsed, without any amelioration of the patient's condition, Dr. Gutierrez determined to give enemata of blood. In three days after these were commenced the patient began to regain her colour, and the night temperature diminished. In a week she was able to take and enjoy her food, and to answer questions put to her. After the blood of eighteen lambs had been used, the cough had entirely disappeared; there was no fever, and the patient was able to get up and walk about; her colour had quite returned, and her spirits had regained their elasticity.

CHYLOUS ASCITES.

THE existence of cases of chylous ascites has been called in question by many observers. Some have asserted that all reported cases of this condition were merely of an inflammatory or cancerous nature, in which the products of the morbid processes had undergone intense fatty degeneration. M. Guinochet, of the Hôpital Tenon, has endeavoured to set this question at rest, and apparently satisfactorily. A patient suffering from a peritoneal effusion, believed to be largely reinforced by the escape of normal chyle into the serous sac was experimented upon in the following fashion: Two punctures were made, partly to relieve the tension and also to ascertain the chemical composition of the ascitic fluid. Thus the chemistry of the fluid was determined whilst the patient existed on ordinary diet. Before ascertaining whether any modification of the diet would be followed by a corresponding change in the chemistry of the ascitic fluid, the patient was placed upon milk alone, in which as much butter was emulsionised as the patient could tolerate. If the peritoneal effusion were really derived from the lymphatics, the fluid withdrawn after the administration of a diet so rich in fats as that mentioned should exhibit corresponding changes, not only in an actual increase of the fat, but also in the presence of butyrine—an article which does not occur normally in ordinary human fat, but which would be present in the chyle if butter were an article of consumption. The analysis made by M. Guinochet fully satisfied these requirements.

CHOLERA SCARES.

WHENEVER cholera is prevalent on the continent of Europe we get a number of cholera scares, often due to the unfortunate practice of registering cases of acute diarrhœa under the name of English cholera or some similar term. But the latest of these scares seems more than usually unjustifiable. It occurred at an inquest held in the East of London on the body of a young man, who, after having been to the Docks with another lad and having there eaten a large quantity of nuts and beans which were being unloaded, was, together with his companion, seized with vomiting and purging. The companion recovered, but the elder of the two young men, after improving, passed a quantity of blood, and died some five days subsequent to his visit to the Docks. According to the daily press, the jury are stated to have recorded a verdict in accordance with the medical testimony, that deceased died from "cholera." We, on the other hand, hold that such verdict was altogether opposed to the medical testimony, which gave a clear history of death due to the effects of the consumption of nuts and beans in the Docks. No inquiry as to the precise nature of the nuts and beans seems to have been made, whereas there can be no doubt they produced the illness in both of the young men, and led to the death in question. Juries, as well as others who have to do with specifying causes of death, would do well to be more careful, because erroneous certificates or verdicts are likely to do us a national injury, and there is absolutely nothing to be gained by carelessness as to the nomenclature of the affection [illegible] question.

THE KIDNEY IN DIABETES.

In a memoir lately published ("Le Rein dans ses Rapports avec le Diabète," Paris, A. Coccoz), Dr. P. S. Inglessis gives the results of his observations upon the renal changes that accompany diabetes mellitus—changes which he avers are more frequent than is commonly admitted. The most constant is hypertrophy of the kidney, a condition doubtless related to the polyuria that is mostly the chief indication of the functional derangement of the organ. This hypertrophy is, according to the writer, characterised not only by obvious enlargement of the kidney, but histologically by a notable increase of the cells of the convoluted tubules. Whilst renal hypertrophy characterises the earlier stages of the disease, renal inflammation is more common in the advanced period. Parenchymatous nephritis is the usual type, but it is difficult often to eliminate all other causes besides diabetes in many cases. In some, however, there is no question of the direct relation between the two affections.

DR. LANGENBECK.

THE numerous friends and patients of the eminent surgeon, Dr. Langenbeck, body physician to the Emperor of Germany, are to be congratulated that he has been dismissed from the Klinik perfectly cured, eleven days after the performance of an operation for cataract by Dr. Hermann Pagenstecher. His Imperial Majesty and many others have sent congratulatory telegrams and messages to the distinguished patient, and to the scarcely less eminent ophthalmic surgeon.

FOREIGN UNIVERSITY AND MEDICAL INTELLIGENCE.

Kharkoff.—Dr. P. Kovalevski, Extraordinary Professor of Neurology and Psychiatry, has been appointed Ordinary Professor.

Bordeaux.—Dr. Demons has been appointed to the Professorship of Clinical Surgery.

Graz.—Dr. Anton Wölfler, a former assistant of Billroth's, has been appointed to the Professorship of Surgery, vacant by the resignation of Professor von Rzehaczek.

Kazan.—Dr. Sasezki has been appointed Professor of General Pathology and Therapeutics, and Dr. Khomyakoff Professor of Clinical Medicine.

Lyons.—Professor Testut has been appointed Professor of Anatomy, and Dr. Fochier Professor of Clinical Midwifery.

Prague (German University).—Dr. Otto Kahler has been appointed Professor of Special Medical Pathology and Therapeutics.

Dresden.—Dr. Ganzen has been appointed Chief of the Lunatic Department of the Town Hospital, in succession to Professor Kraepelin, who has gone to Dorpat.

WE understand that the Commission appointed to inquire into the results of M. Pasteur's inoculations have prepared a draft report, but that they withhold it until they can ascertain the accuracy of the reports of fatal cases which have recently been published. The experiments conducted by Mr. Victor Horsley have, we learn, so far fully confirmed M. Pasteur's statements; but they are not yet complete, and will therefore be left to be detailed in the report.

IT is stated that after the beginning of next year the vacation courses of the Vienna Medical Faculty will be discontinued.

PROF. ARLT, the renowned ophthalmologist of Vienna, is, we regret to learn, suffering from gangrenous thrombosis of the leg.

A MEMORIAL is to be erected to commemorate the death of Mr. Isaac Ratcliffe Lane, of the Army Medical Staff, who was killed at Hasheen, Soudan; it is to be in the form of a "Latten" Brass from the works of Mr. Gawthorpe, of London. He was the youngest surgeon in the British army.

HEALTH OF THE ARMY.

No. II.

THE average strength of the European troops in India in 1884 was 55,252. The ratio of admissions into hospital per 1000 of the force was 1495, of deaths 13·03, of invaliding to England 31·87, and of constantly non-effective from sickness 67·37; the admissions and mean sick were somewhat above, but the deaths and invaliding considerably under the average of the preceding ten years.

The force in Bengal averaged 33,716; the admissions were 1645, the deaths 12·10, the invalids sent home 31·82, and the mean daily sick 70·86 per 1000. Except the deaths and invaliding, these ratios are above the average of the ten years. The death-rate was 6·64 per 1000 under the average, the reduction having taken place chiefly in cholera, diseases of the digestive system, in those of the nervous system, and in paroxysmal fevers. The Lahore division furnished the highest ratio of admissions—2486 per 1000; but it was also very high in the Peshawar, Gwalior, and Meerut divisions, the excess in all of them being chiefly due to the prevalence of fevers. The lowest ratio of admissions was in the Presidency and Oudh divisions. The death-rate was highest in the Gwalior division, amounting to 22·94 per 1000, and lowest in the Saugor and Sirhind divisions, in which it was 5·75 and 6·78 per 1000. Enteric fever was the cause of 423 admissions and 111 deaths, being in the ratio of 12·5 and 3·29 per 1000, both higher than in 1883 and above the average of the preceding five years. It was most prevalent in the second and third quarters of the year, 161 cases and 33 deaths having occurred in the former and 129 cases with 43 deaths in the latter. The disease was widely spread, cases having occurred at forty-seven different stations. Those which furnished the largest number were Lucknow, Morar, Sitapur, Mooltan, Fyzabad, Meerut, Agra, and Rawal Pindi. At Sitapur it was attributed to "an insanitary condition of the latrines near the barracks," and at Fyzabad to adulterated milk, but at none of the other stations could any special cause be traced. At Lucknow the medical officer in charge attributes its origin to "the influence of unaccustomed heat on young persons. This theory is strengthened by the fact that 29 out of 53 cases (in the cantonment) occurred in the Derbyshire Regiment, the most recent arrival in India, and which contained a larger proportion of young soldiers than any other corps in the garrison."

Cholera gave rise to 71 admissions and 45 deaths, being 2·1 and 1·33 per 1000 of the strength. Meerut furnished 28 cases with 13 deaths; Allahabad 10, with 5 deaths; and Dinapore 9, with 7 deaths. They occurred chiefly in the third and fourth quarters of the year. Three fatal cases of hydrophobia are returned: one at Sialkot, in which the period between the infliction of the bite and the death of the boy was 29 days; one at Bareilly, in which it was 81 days; and one at Umballa, in which it could not be exactly ascertained. Under the head of poisons 72 cases, with 1 death by delirium tremens, and 250 cases with 6 deaths by alcoholic poisoning are returned, being in the ratio of 9·55 admissions and ·21 deaths per 1000 of strength from the direct effects of intemperance. There were 22 cases of poisoning by hill nuts, "a species of jatropha," in a detachment on the march between Roorkee and Chakrata; they all recovered. There were during the year 1 judicial, 4 homicidal, and 12 suicidal deaths.

The average strength in Madras for the year was 10,812, the admissions into hospital were 1106, the deaths 9·25, the invaliding to England 32·37, and the mean sick 59·14 per 1000. The admissions were higher, but all the other ratios lower, than in 1883, and all except the mean sick were considerably under the average of the ten years. Rangoon was the station, exclusive of depôts, at which the ratio of admissions was highest, amounting to 1553 per 1000, and Port Blair that at which it was lowest. Of the larger stations

Bangalore had the lowest death-rate—3·98; and Madras and Palaveram the highest—14·92. There were 19 cases of small-pox, with only 1 death; 9, including the fatal case, at Bangalore; 4 at Madras, 2 at Kamptee, 2 at Secunderabad, 1 at Rangoon, and 1 on the march; the disease was epidemic over Southern India. Enteric fever was more prevalent, but less fatal, than in 1883, the admissions being 11·9 and the deaths 1·66 per 1000 of the strength; 60 cases and 1 death occurred at Bangalore; 39, with 10 deaths, at Secunderabad; and 15, with 3 deaths, at Kamptee. No definite cause could be traced for these outbreaks, which occurred chiefly among young soldiers, many of them recent arrivals in India. One-half of the cases and deaths occurred in the third quarter of the year.

Although cholera was very prevalent in most of Southern India, the troops suffered very little from it, the cases having only amounted to 1·1 per 1000; of 12 admissions, however, 10 terminated fatally, and one invalid from Madras died of cholera on the passage home. Three cases occurred at Madras and four at Bangalore, where the disease was epidemic among the civil population. The troops in Madras appear to be very exempt from phthisis, the deaths in 1884 having only amounted to ·55 per 1000, and the average of the preceding five years to ·97 per 1000. Diseases of the digestive system gave rise to a higher ratio both of admissions and deaths than any other class, the former having been 229 and the latter 2·78 per 1000 of strength, the great mortality being due to hepatitis and abscess of the liver, the deaths by which amounted to 2·13 per 1000.

In Bombay the average strength for the year was 10,724; and the admissions were 1415, the deaths 19·70, the invalids sent to England 31·52, and the mean sick 64·70 per 1000. The admissions and invaliding were under, but the deaths and mean sick above, the average of the preceding ten years. The increase in the death-rate was chiefly due to cholera. The highest ratio of admissions, exclusive of the sanitaria, was at Quetta, where it amounted to 2001, and of deaths also, if the small station of Baroda be excepted and troops on the march. The latter suffered most severely, 61 deaths out of a total of 204 in the command, having occurred in an average annual strength of 577. The decrease in the admissions was shown chiefly in cases of paroxysmal fever, but there was scarcely a corresponding reduction in the mortality. Compared with the results for 1883, there was an increase in enteric fever and the deaths from it. It prevailed throughout the year, but especially in the first quarter, at Karachi, and in the last two quarters at Quetta. The prevalence at these stations could not be traced clearly to any insanitary condition of the stations. At Ahmednagar it was attributed to a contaminated milk-supply, and at Deesa, Nasirabad, and Baroda to the water. The cases at Quetta amounted to 27·9 and the deaths to 9·3 per 1000 of strength. Cholera was the cause of 66 admissions and 52 deaths, being in the ratio of 6·2 and 4·85 per 1000; of these, 48 cases and 39 deaths occurred in the 2nd Battalion, North Staffordshire Regiment, on the march from Quetta to Mhow. The disease broke out in it at a camp in the Bolan Pass, and could not be traced to any apparent cause. Exclusive of those among troops on the march the cases amounted to 1·39 and the deaths to 1·03 per 1000, or double the average of the preceding five years. Deolalee and Mhow furnished the largest number of deaths; no local insanitary condition could be found to account for it, but the disease is stated to have been prevalent among the civil population. Diseases of the digestive system were, next to paroxysmal fevers, the cause of the highest ratio of admissions, and, with the exception of cholera, also of deaths. Among the injuries there were seven admissions and six deaths by lightning, which struck the roof of a barrack supported by iron girders at Nasirabad, passed along the punkah wires in the upper storey, killing a man sitting on his cot, to the lower storey, where it killed five men [illegible] at a table. A severe accident occurred at Kirkee, some men employed in filling shells; the powder exploded, injuring eight men, of whom 2 died, one from fracture of thigh and shock, the other from tetanus supervening on compound fracture of both legs.

The force in Lower Egypt, including the small permanent garrison of sixty men at Suakim, averaged 6468; the admissions to hospital were 1266, the deaths 11·59, the invalids sent home 49·47, and the mean sick 76·85 per 1000. The most prevalent disease was syphilis, by which 266 admissions per 1000 of strength took place; and the most fatal was enteric fever, the death-rate by which was 4·95. There were 25 cases of small-pox with only 1 death; the disease was very prevalent among the natives at Cairo, and vaccination greatly neglected. The admissions by enteric fever were 24·9 and the deaths 4·95 per 1000; it was most prevalent and fatal at Alexandria, where the ratios were 59·7 and 11·56 per 1000; the greatest number of cases came from Ramleh Barracks. The medical officer in charge is of opinion that "the chief cause to be assigned for the prevalence of fever in these barracks must be looked for in the saturation of almost the whole of the soil underneath them by sewage matter in past years, caused by the cesspits and drains being built without inverts, the bottoms being thus left open, allowing the sewage to percolate into the soil." Sunstroke was the cause of 46 admissions and 4 deaths, of which 24 with 1 death took place at Abbasiyeh, "due to the reckless and imprudent exposure of insufficiently protected heads to the sun by young soldiers just arrived from home, aided, no doubt, in some cases by drink." The admissions by diseases of the eye amounted to 53 per 1000, but, with the exception of 1 of purulent ophthalmia, all the cases were of simple conjunctivitis. At Suakim, in an average force of 60 men, chiefly sappers, 3 deaths occurred, all from sunstroke. Fever was very prevalent among them, but did not prove fatal, and no case was returned as "enteric."

In the appendix to the report there is a medical history of the Nile expeditionary force from March 18th, 1884, to July 31st, 1885, by Surgeon-Major Mouat, which may be noticed here. The estimated strength of the regular forces employed with the expedition was 10,771; the admissions into hospital were 8953, the deaths 557, and the number invalided 630—in a period of 500 days. These numbers, therefore, give the *annual* ratio of 607 admissions, 37·75 deaths, and 42·70 invalided per 1000 of strength.[1] Of the deaths, 84 were men killed in action and 42 who died subsequently of their wounds, making a total of 126, or 8·54 per 1000, and leaving 29·21 per 1000 from other casualties and disease. There were 41 cases of small-pox, with 5 deaths—a high proportion in a vaccinated population, but probably due to the circumstances in which the troops were placed on field service. The disease is stated to have been very prevalent among the natives at several of the stations. The greatest cause of mortality was enteric fever, of which 760 cases were admitted, and 277 died. These numbers give the *annual* ratio of 51·51 cases and 18·77 deaths per 1000, the latter being almost exactly half of the total mortality. Upwards of two-thirds of the cases occurred among men under twenty-five years of age, and three-fifths among those under five years' service. At Wady Halfa, where 178 cases and 47 deaths occurred, the disease was considered to arise, to some extent at least, from the insanitary condition of the camp ground and its vicinity, but elsewhere no specific cause could be assigned. The high death-rate was doubtless due in a great degree to the unfavourable conditions for treatment in which the cases were placed, the necessity for moving them without reference to their state, and the exhausting heat to which they were exposed in the desert. There were only 5 cases of scurvy during the whole time under report. Of sunstroke 64 cases were admitted and 13 died, being in the *annual* ratio of 4·34 and ·88 per 1000. Considering the circumstances under which the force was serving, this seems to be a very low proportion. The admissions for conjunctivitis were only 486, or 33 per 1000, considerably under the proportion among the troops in Lower Egypt; they were "mainly due to irritation from pustules of fine sand blown through the camp during dust storms." The admissions and deaths from dysentery and diarrhœa were in the annual ratio of 124 and 4·07. Towards the end of the campaign a too free indulgence in fruits and tinned provisions by the men retiring down the river was a fertile source of bowel affections. Of 39 deaths from injuries, exclusive of those received in action, 37 were by drowning. The wounds received in action occasioned 241 admissions, 42 deaths in hospital and 84 on the field of battle. A classified return of the wounds and injuries admitted into hospital is appended to the Report, and Dr. Mouat has given copious notes respecting their nature and extent and the treatment adopted.

The average strength of officers was 600. The admissions among them were in the *annual* ratio of 625, and the deaths of 49·88 per 1000; of the latter 17·03 were in action, or officers

[1] Surgeon-Major Mouat, in his report, has calculated the ratios upon the average strength of the force for the whole period, but as that extended over 500 [illegible] reduced them to the *annual* ratios.

[illegible] moderate.

who died in hospital from their wounds. The invaliding amounted to 128 per 1000. These ratios are all considerably above those of the troops. Enteric fever was the cause of 57·2 admissions and 18·25 deaths per 1000 of strength, being very nearly the same as among the non-commissioned officers and men. The report gives an analysis of the wounds and injuries received in action and of the operations performed.

The strength of the men of the Royal Navy, Canadian voyageurs, kroomen and others attached to the expedition, was estimated at 2452; the admissions among them were 671, the deaths 71, and the invalided 16. Of the 71 deaths, 60 were due to disease, 3 to accident, and 8 to wounds received in action. We have not reduced their numbers to the *annual* ratios, as the information regarding this portion of the force is in some points defective.

ERRATA.—In the first part of this article, published in our last, several errors of importance unfortunately escaped correction owing to delay in the return of the proof. Thus, on page 370, line 18 from the commencement of the article, the average death-rate of the troops should have been stated as 5·33, not "8·42"; in line 5 of the second paragraph on page 371, for "Royal Engineers" read *Household Cavalry*, the sickness ratio of which arm was 35·19, whilst that of the Foot Guards was 57·53, instead of "29·34" and "48·35" per 1000 respectively. On page 371, first column, line 25 from bottom, insert "with the exception of the admissions" after "higher"; line 10 from bottom and elsewhere, for "Cottonua" read *Cottonera*; 4th line from bottom, for "occurred" read *arrived;* second column, line 17, for "7·52 and 7·01" read *7·52 and 7·09;* page 372, first column, line 7, for "530" read *539;* line 29, for "some" read *seven;* two lines further on, for "moved" read *arrived;* in second line of third paragraph of same column, for "22·3" read *22·03;* in following paragraph, lines two and three should read "was 985; the ratio of admissions into hospital was 1198; of deaths 11·17," &c.; in last line of the column, for 38·33 read *38·23;* finally, in second line of second column, for "and the admissions and mean sick" read *also, with the exception of the mean sick,* &c.

THE OUTBREAK OF ENTERIC FEVER AT LANCING COLLEGE AND SHOREHAM.

THE following is the gist of a report to the Steyning Rural Sanitary Authority by Dr. C. Kelly, sanitary officer of health for West Sussex:—

'GENTLEMEN,—I have to report to you an outbreak of enteric fever at Lancing College, of which I received information on the 23rd instant. On visiting the College on that day with Dr. Fuller, I found that there had been fourteen cases of fever, of which two had died and three had been removed, so that there were then nine boys ill with the disease. Three boys were admitted into the ward on July 7th, another on the 10th, three on the 12th, three on the 16th, and two on the 18th, but some of them felt ill two or three days before going into the ward. The dates of admission seemed to point either to great variation in the incubation period of the disease, or to a source of infection spreading over an interval of several days. Five of those attacked were in a dormitory in the second master's house, and four were in the school house, of whom three were in one room, and one patient, being very ill, was in a separate room. Two of the patients had died, and three had been removed before the date of my first visit. Lancing College contains about 200 boys, a head master, eleven masters, eight men servants, and fifteen or twenty women servants. Besides these, about sixty men are employed near the College in erecting a large chapel, but they had no direct communication with any part of the College. The College stands upon a spur of the chalk downs at an elevation of over 200 feet above the sea; on the north, south, and east sides the ground slopes rapidly away, while it rises to the west. The situation is open, airy, and dry, the grounds extending over an area of 160 acres. To the east of the College, and at the bottom of the hill, there is a large level cricket ground, between a large clump of trees and the river Adur. About a mile and a half away (in a straight line) to the south-east is the town of New Shoreham, where at this time there was also a large outbreak of enteric

'Ca

"The water-supply to the College is obtained from a fine spring at the base of the chalk downs, whence it is pumped up to a reservoir on the hill side, and thence is conveyed by a pipe across the river Adur up to the College buildings..... The same Company supply various other places, as Portslade and Southwick; but, as there was no outbreak of fever in either of these towns, it did not seem probable that there was any pollution of the water-supply. The drainage of the College is carried away to an outfall to the north-east of the buildings, in a large field, where it is used for irrigating the soil.....There was nothing in the condition of the water-supply or of the drainage system which seemed to account for the outbreak. There is a farm on the College grounds where a few cows are kept to supply milk to the boys; no butter is supplied from this dairy, and all the milk is sent up for the use of the College. The cows are all in good health, and yielded plenty of milk. There had been no cases of illness among those who worked on the farm. The eggs and milk came from the College farm, the bread was made on the premises, the cheese and butter came from Dorsetshire, and the meat from London; so that very little, if anything, came from local sources outside the College grounds. The boys would frequently go to Shoreham in the course of their walks, and they would often go to a confectioner's to buy pastry or sweets; but, except in this way, there was very little communication between Lancing College and Shoreham; and yet the fact that there was a simultaneous outbreak of enteric fever at Shoreham pointed to, or at least suggested, a common cause. In the College cricket field there are two buildings, one used by the cricketers and one used as a 'tuck shop.' Every afternoon Mrs. X., who lives at Shoreham, goes over to the 'tuck shop' to sell her goods. She obtained sweets and lemonade from Brighton, fruits of various kinds from Shoreham, and she had lately been supplying some cream which she maintained did not come from Shoreham, but from the Pad Inn, close to the entrance to the College grounds [where one cow was kept].....The cow yielded about two and a half or three gallons daily, but no accurate measurements were ever taken, nor were any accounts kept, as Mrs. X. paid each day for what she had. But the landlady remembered that she often called for cream as she went by, after the strawberries came in, and she recollected serving her with three pints on one day and two pints on another, besides smaller quantities on other days. She further remembered that these larger quantities were sold on the occasion of the Old Boys' match, because her husband was present, and he saw Mrs. X. coming up to the grounds from his house. This was a two days' match, and it was played on Friday and Saturday, July 2nd and 3rd. On such an occasion a great many were present, and Mrs. X. made provision for it by getting more fruit and cream.....Every boy who was ill had partaken of strawberries and cream, but it was also true that numbers partook of the cream who were not ill at all. A young lady, Miss H., who was present at the Old Boys' match, fell ill at Brighton with enteric fever five days after the match, and some boys who drank from the same portion of cream of which she partook escaped the disease altogether. Some boys who had been rowing on the river the same morning, being too young to play in the match, came back with one of the masters early in the afternoon; tired and hot, they refreshed themselves liberally with the fruit and cream, yet not one of them was attacked. Of the boys who fell ill with the fever, six were in the first eleven, and played in the match. No one can tell how many of those present regaled themselves with fruit and cream; but it was evident that far more escaped illness after partaking of them than the number of those attacked. It has been before stated that the dates of incubation varied very much, so that unless there is a great variation in the incubation period, it is hardly likely that a boy should take infected cream on July 2nd or 3rd, and be admitted into the ward on July 7th, or that Miss H. should fall ill about the same time. It seemed clear that the cream at the Pad Inn was not at fault; and certainly if it were, it could not account for the Shoreham outbreak, as no one from that town drank this milk. Dr. Fuller, the medical officer to Lancing College, from the first expressed a firm belief in the cream being infected. He was attending at this time several patients in the Shoreham Workhouse who were suffering from enteric fever, and they obtained milk from a dairy belonging to A., and those who were ill were chiefly women and children who drank a good deal of milk. Some men who worked on a railway bridge near A.'s dairy at the end of June drank skim milk supplied

by A., and three of these men fell ill, one of whom was the man who has been mentioned above as lying ill at Portslade. On visiting this dairy Mrs. A. showed by her books that Mrs. X., who supplied the 'tuck shop,' had had cream from her from June 25th to July 3rd, so that there must have been in the cricket field cream from two sources—one from the Pad Inn and the other from A.'s dairy. Mrs. X. had nearly a quart of cream from A.'s dairy on Friday, June 25th, a quart on the 26th, a quart on the 28th, a pint on the 29th, a pint on the 30th, ninepennyworth on July 1st, and sixpennyworth on July 3rd, after which date she had no more. If this cream were infected, those who drank of it were liable to infection during the whole of the week previous to the Old Boys' match on July 2nd and 3rd, as Mrs. X. supplied cream to no one else but those who frequented the cricket field. Further inquiry showed that there was a cricket match on Saturday, June 26th, in the College grounds, between the boys and an eleven from Tunbridge, and on this day a quart of cream was taken up by Mrs. X., who probably had some more on the same day from the Pad Inn. I think it is clear that these creams were kept in separate vessels. Mrs. X. brought A.'s cream in an oval tin, holding about half a gallon, while the cream from the Pad Inn was put in a jug or in a tin belonging to the inn dairy. The liability to catch the disease was probably greater on June 26th and on the first three days of the following week than on July 2nd and 3rd, when only small quantities of cream were obtained from A.'s dairy, while three pints were supplied on July 2nd from the Pad Inn dairy, and a quart from the same place on July 3rd. The price of cream at A.'s dairy was 2*s.* a quart, so that 9*d.* would purchase three-fourths of a pint, and 6*d.* would represent half a pint. Miss H. was at the match on June 26th with her sister, and they had on that day some cream, and it must have been on that day that she became affected; the cream which she had at the Old Boy's match, and which others shared without falling ill, was probably of good quality. The various dates on which the boys fell ill can now be accounted for, since the source of infection was present not for one day only, but for a space of seven or eight days. Miss H.'s sister was poorly for a few days, and, as her temperature on one occasion rose to 103° F. it is probable that she also was in some degree infected on June 26th. Of the boys who were attacked, one was fourteen years of age, one fifteen, two sixteen, seven seventeen, and three eighteen. The reason why none of the younger boys were attacked may be accounted for by the fact that the older boys having more pocket-money were able to buy the fruit and cream, while the younger ones put up with some cheaper form of refreshment. When it was quite clear that cream from A.'s dairy had been supplied during the last week in June, and when others had failed about the same time at Portslade and New Shoreham who had been drinking milk from the same dairy, it seems almost certain that there must have been a common origin for the outbreaks at the College and at Shoreham, and that the milk from A.'s dairy was the common source of infection. This view is confirmed by the fact that there has been no fresh case of fever at the College since July 18th, and the cream-supply was stopped on July 3rd, while there have been many fresh cases in Shoreham since that date amongst those who continued drinking this milk."

Dr. Kelly then proceeds to give a detailed description of the drainage and water-supply at A.'s dairy, with the result that he shows leakage from the drain into the well was at least a probability. He then states, "There was no case of illness in A.'s house, nor had there been any for a long time. There is no evidence of anyone having had enteric fever just before the outbreak, so that the sewers might have become infected with the discharges from such a case, but enteric fever has, in recent years, been very common at Shoreham, and the sewers are not very well ventilated..... There were six cows at A.'s dairy, but one of these was not in milk; they were said to be in good health and to yield plenty of milk. They were not seen until July 26th, so that their condition during the last fortnight of June could not be ascertained. Mr. Knight of Brighton, who has recently examined the cows, has found nothing in their condition to account for the outbreak. All proper precautions have been taken by Dr. Fuller as to the disinfection and burying of all discharges, and the drains have been well flushed. As no fresh cases have occurred since July 18th, the outbreak of enteric fever is now at an end, and the remaining patients are all recovering. The outbreak has, therefore, been due not to any defects in the sanitary arrangements of the College itself, nor to any pollution of the water-supply, but to impure cream being taken under conditions which cannot occur again. The well at A.'s dairy has been closed, and good water is now supplied there from the public main."

Worthing, July 29th, 1886.

BRITISH DENTAL ASSOCIATION.

ONE of the most successful meetings of the increasingly popular British Dental Association was held last week at the School of Mines, Jermyn-street, under the presidency of Sir John Tomes, the president of the year, Mr. Richard White, being unfortunately too ill to attend.

Of the papers read on the first day, that of Mr. George Cunningham, on the Relation of Dentistry to the State, was perhaps of the most general interest, and the moderation and practicability of the view expressed are sure to meet with general approval. He recognises fully that the army surgeon, who is already expected to be a veritable "Admirable Crichton" in surgery, medicine, midwifery, drill, ambulance, a capable administrator, able to select suitable sites for camps, to be competent to perform complex analyses of food and water, &c., cannot be expected to be likewise a dental specialist, but still he maintains that something might and ought to be done in conservative treatment of the teeth, something more than the radical cure—extraction; in fact, that the army surgeon should have to produce a certificate of having attended a course of lectures and gone through a course of clinical instruction in dental operative surgery at a general or special hospital. It seems, several have gone further than this, and qualified in dental surgery at the Royal College of Surgeons. The "regulation army extracting case" seems to be of a very antiquated description, the key, of which the modern dentist has had no experience, and forceps, which it would be difficult for a specialist to know for what purpose they were intended, are the armamentaria. The "stopping case," on the other hand, contains gold foil, as if the most skilful dental surgeon was expected, but omits a mirror to see the cavity, and tweezers to insert a dressing. We cannot now discuss further this paper, but we are sure that the Army Medical Department, who have done so much in recent years to promote the efficiency of the service, will improve and modify their dental equipment.

Messrs. Morton Smale and Hutchinson read an excellent paper on Dental Education, and very strongly urged that every dental student should take the L.R.C.P. and M.R.C.S. under the Conjoint Scheme in which we agree; they or one of them, should, however, be regarded not only as an advantage, but as a *sine qua non*.

On Friday the great attraction was the Demonstrations, principally in gold fillings, at the Dental Hospital of London, and amongst the patients there was a well-known dental practitioner, which caused considerable amusement. Electricity, both as an illuminator and a motor, was conspicuous in the exhibit of dental apparatus. The day's proceedings terminated with the annual dinner, under the presidency of Sir Edwin Saunders, which took place at the Criterion. Sir Edwin, in a very apt and appropriate speech, proposing the toast of the Queen, enlisted the sympathies of his audience by stating that Her Majesty had once observed to him, "Yours is a most useful profession; for while some require the services of the oculist, a still smaller number the aurist, almost all, sooner or later, have need of those of the dentist." The principal toasts were that given by Mr. Sibley, "The Prosperity of the British Dental Association," to which Mr. Frederick Canton, the hon. secretary, replied, and "The Royal College of Surgeons," proposed by Mr. Smith Turner and responded to by Professor John Marshall; several others followed. The meeting was a great success, being well attended.

The business and festivities of the week culminated in the garden party, given by Sir Edwin Saunders, at his charming residence, Fairlawn, Wimbledon, which was a complete success, notwithstanding that many members of the profession and personal friends of Sir Edwin and Lady Saunders were prevented from attending. H.R.H. Princess Mary of Cambridge (Duchess of Teck) wrote expressing her regret that unforeseen circumstances prevented her from being present, moderate... ended and wished.

WILLS OF MEDICAL MEN.

THE will and codicil of Mr. Wm. White Cooper, F.R.C.S., F.R.G.S., late of 19, Berkeley-square, who died on June 1st last, were proved on July 24th by Dame Mary Elizabeth Cooper, the widow, and Mr. George Cox Bompas, the acting executors, the value of the personal estate amounting to upwards of £28,000. The testator bequeaths £500, and all his household goods, furniture, pictures, plate, wines, and effects to his wife. All his real estate and the residue of his personal estate he leaves upon trust to pay the income to his wife for life; at her death he gives £1000 to each of his daughters, and the ultimate residue is to be held upon further trust for all his children in equal shares.

The will and two codicils of Thomas Boycott, M.D., late of 46, Montagu-square, who died on May 12th last, were proved on July 16th by Mr. Alfred Paget Humphry and Mr. Hugh McNab Humphry, the executors, the value of the personal estate exceeding £17,000. There are bequests to his wife, daughters, and son-in-law, and the residue of his property the testator leaves upon trust for his wife for life, and then for all his children in equal shares; his son-in-law, Mr. A. P. Humphry, to take the share of his deceased daughter, Elizabeth.

The will of Mr. Francis Mason, F.R.C.S., surgeon of St. Thomas's Hospital, late of 5, Brook-street, Grosvenor-square, who died on June 5th last, was proved on July 23rd by Mr. Edmund Routledge and Mr. Henry Sturt, the executors, the value of the personal estate amounting to over £5000. The testator bequeaths to his wife, Mrs. Jane Mason, the cash in the house and at his bankers, and his furniture, plate, household effects, horses, and carriages; and there are legacies to his own and his wife's godchildren, executors, domestic servants, and coachman. The residue of his real and personal estate, in default of children, he leaves as to the income of one moiety to his wife for life, and subject thereto for his nephews and nieces, the children of his late brother, John Nicholas Mason.

The will of Mr. Hutchinson Royes Bell, formerly of 44, Harley-street, but late of 12, Queen Anne-street, Cavendish-square, surgeon, who died on June 15th last, was proved on July 31st by John Hougham Bell, M.D., the brother, the surviving executor, the value of the personal estate amounting to upwards of £12,000. The testator leaves his real estate at Dunkeeling, Yorkshire, to his brother Mark Sever Bell, and legacies to his brother John Hougham Bell and to his sisters. The residue of his property he gives to his said two brothers in equal parts.

The will and codicil of Charles Girdlestone, M.D., late of the Château de la Falaise, Biarritz, who died on June 14th last, were proved in London on July 27th by Mrs. Eliza West Girdlestone, the widow, and Mr. Reginald Henry Thorold, the executors, the value of the personal estate being under £2000. The testator gives all his real and personal estate to his wife.

The will of John William Mudge, M.D., J.P., Deputy Inspector-General of Hospitals, on the retired list of H.M. Indian army, late of Middleham House, Ringmer, Sussex, who died on May 3rd last, was proved on July 20th by Mrs. Julia Mudge, the widow, and Major-General Lambert Henry Denne, the executors. The testator bequeaths £200, and all his furniture, plate, pictures, books, wines, and consumable stores, household goods and effects, horses and carriages, to his wife; and legacies to his two daughters and to a cousin. The residue of his real and personal estate he leaves upon trust to pay the income to his wife for life, and then for his two daughters in equal shares.

The will of William Benjamin Scott, M.D., late of 16, Stonebridge Park, Willesden, who died on November 2nd last, was proved on July 19th by Mr. Alfred Roots and Mr. George Roots, the executors. The testator leaves all his real and personal estate, except what he succeeded to from his mother, to Elizabeth Roots.

The following legacies have recently been left to hospitals and other medical charities:—Mr. Charles Charlesworth, of Heaton, near Bradford, Yorkshire, £500 to the Bradford Fever Hospital.—Mr. Robert Charles Ransome, J.P., of Ipswich, £100 each to the East Suffolk Hospital and the Suffolk Convalescent Home, F[illegible]

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Kensington.—The death-rate for this important parish during 1885 was 16·1 per 1000. The deaths from the so-called seven principal zymotic diseases were 57 more than in 1884, but 67 below the corrected decennial average. Dr. Dudfield's report deals with a large number of subjects having direct or indirect bearing upon the sanitary state and healthiness of his district as a portion of the metropolis, and he hence reviews the subject of scarlet fever in relation to disease in the cow, the state of preparation maintained in view of a possible importation of cholera, and the arrangements in force as to the removal of infectious cases, whether as regards ambulances or by means of the hospitals provided in and outside the metropolitan area. Indeed, the report forms an excellent summary of all the action taken hitherto by the Metropolitan Asylums Board in the fulfilment of their important duties. Pending the compulsory notification of infectious diseases, a voluntary system has been organised in Kensington, news being received as to deaths or cases of infectious diseases from registrars, relieving officers, the Asylums Board, the resident medical officers of the hospitals and dispensaries, the postal authorities, clergymen and district visitors, and at times from private medical practitioners; and, reviewing the results of this system, Dr. Dudfield shows by means of statistics that when the period of eleven years during which the system has been in operation is compared with a corresponding period antecedent to its inauguration, there has been a diminution in the number of "zymotic diseases" to the extent of 1441. He does not doubt that many causes have together contributed to this result, but he evidently cannot dissociate it from the early information received from the sources indicated. In addition to 956 sublet houses already registered in the parish, notice has been served in respect of 546 houses let in lodgings, and although the owners of these houses in several instances profess that their registration will do them an injury, yet experience is so far in an opposite direction, and in Kensington it is believed that registration will come to be regarded as a guarantee that the house is in a good condition, as soon as the vestry's instructions have had time to be fulfilled.

Wandsworth District.—In a population of 248,410, the birth- and death-rates for 1885 were 31·6 and 16·8 per 1000, the latter being a lower rate than any obtaining during the previous ten years; and it is interesting to notice that there has been an almost steady diminution in the death-rate during the series of years since 1851-60, when the average rate stood at 20·4 per 1000. The smallest death-rates for last year were 11·2 and 12·4 in Putney and Clapham, and 17·0 and 17·5 in Wandsworth and West Battersea respectively. Amongst the special causes of death, diarrhœa is referred to in connexion with the whole of the metropolis, and it is shown in a tabular form that there is a distinct relationship between excesses of death from this disease and high temperatures, the relationship being attributable to the rapid production of fermentative and putrefactive changes. The water-supply suffers from changes of temperature in so far as that which is derived from the Thames is concerned. Thus, the extremes of temperature for that supply have been 37·0° and 70·5° F., as compared with a variation between 53·6° and 58·1° only in the deep well-water distributed by the Kent Company. The need for a uniform constant service is urged in the report. In the Local Summaries each of the six medical officers of health presents a separate report.

Leicester Urban District.—Dr. Henry Tomkins, in issuing his first annual report on the sanitary condition of this borough, deals separately with all the more important circumstances affecting the health of the population, and in several respects he advocates that further progress should be made. Thus, Leicester being well provided with public slaughter-house accommodation, and cleanliness being so prominent a matter to hold in view in connexion with all food supplies, he urges that the time has come for the gradual abolition of the private slaughter-houses from amongst the houses of the people. He also points out that the existing borough infec-

tious hospital, erected during a period of small-pox epidemic, does not properly meet the requirements of the district. It is freely admitted that the hospital has done, and is still doing, excellent service; but the accommodation provided is unsatisfactory, the means for separating cases needing special isolation are most imperfect, and some parts of the structure are old and worn out. Some alterations and extensions were made during the past year, but we fear that nothing short of a good deal of preliminary demolition of existing buildings will place Leicester in the position it should occupy in this respect. Referring to comments which have appeared in this journal as to the failure which has been evident in many towns having hospitals and immediate notification of infectious diseases, to reduce the amount of scarlet fever, it is admitted that as regards Leicester the only feature that one can point to with any sense of satisfaction is the low mortality that has occurred, and this especially as regards those who received hospital treatment. Small-pox appeared in the borough in four instances. All the cases were removed to the hospital outside the borough, and those persons known to have been possibly infected by them were induced to go to the "quarantine" wards, four more subsequently falling ill there, and the remainder being discharged after the lapse of the usual incubation period of the disease. The birth and death-rates for 1885 were 24·4 and 19·4 respectively per 1000; the latter being one of the lowest rates Leicester has experienced. The deaths under one year of age were 193 per 1000 registered births, this being the highest rate, except 218 at Preston, of any of the twenty-seven largest towns, metropolitan and provincial. Of the deaths producing this rate in Leicester, 276 were from diarrhœa.

Warrington Urban District.—On a population of over 45,000 the birth and death-rates for 1885 were 40·25 and 18·45 respectively, the latter rate being the lowest ever recorded in Warrington since statistics have been published. The rate from the so-called zymotic diseases was also a low one. Not a single death occurred amongst the inhabitants from either small-pox or scarlet fever; but of the latter disease 20 attacks were reported, 8 occurring in the workhouse, and 10 of the remainder being removed to the isolation hospital. Enteric fever has been of somewhat common occurrence in a special portion of the town, where sewer emanations and nuisances from pigstyes, stables, and middens are much too common. Since the Corporation opened their infectious hospital in 1877, the number of cases admitted has been 925; of these 27 were admitted last year. The cost of maintaining this very complete establishment was somewhat over £776 last year. But against this may be set the fact that, although Warrington possesses a system of compulsory notification of infectious diseases, Mr. Gornall is able to point out that the number of cases which it is found necessary to remove to hospital has diminished year by year, until it was in 1885 at its lowest ebb. Such a result cannot be otherwise than a substantial financial gain to the community concerned. The existence of the hospital, amongst other things, prevents resort, in times of disease prevalence, to "panic remedies," which are as a rule both costly and altogether unproductive.

Scarborough Urban District.—Dr. Taylor commences his report with a very complete meteorological history of Scarborough during 1885. The death-rate from all causes during the year stood at 16·7, which is by no means unsatisfactory, and the zymotic rate was as low as 0·7 per 1000; the two diseases of the latter class which caused most mortality being measles and diarrhœa. Considerable care has for some years past being exercised with a view of improving the standard of health in this watering-place, and the statistics which are recorded in the report go to show that this action has not been unrewarded. Great care is given to the disinfection of infected houses and articles, and the private sanatorium is spoken of as being of infinite service to the town for the immediate isolation and treatment of infectious disorders. Great improvements have been secured in connexion with the water-service, and a large amount of current sanitary work is continually in progress.

Stratford-on-Avon Combined District.—Mr. Fosbroke's re-election to this combination of districts after twelve years' service is evidence that his labours are appreciated, and this the more since the combined authorities desired to make the appointment without any limit as to duration—an arrangement which was objected to at Whitehall on grounds which were "not personal" to him. In other words, the ever-looming County Board Bill still blocks the way in this and in many other directions. The clashing interests of education and health are referred to under circumstances which, it might have been hoped, were such as could not occur in view of the provisions of recent Education Codes. The voluntary system of notifying infectious diseases in this district is stated to work without friction. In addition to the hospital in the Alcester district, it is to be hoped that one will be established for the Evesham joint district before the expiration of the present year. The plans have already been prepared and approved by the Local Government Board. Amongst the important sanitary works that have been dealt with, the completion of the Evesham water-works may be named; a scheme for the supply of Stratford-on-Avon is also wellnigh completed. Evesham and Stratford have revised their bye-laws, and the Alcester authority intend to take action in the same direction.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5876 births and 3400 deaths were registered during the week ending August 21st. The annual death-rate in these towns, which had declined in the preceding three weeks from 20·6 to 18·9 per 1000, rose again last week to 19·5. During the first seven weeks of the current quarter the death-rate in these towns averaged 19·6 per 1000, and was 2·1 below the mean rate in the corresponding periods of the ten years 1876-85. The lowest rates in these towns last week were 11·9 in Derby, 14·4 in Wolverhampton, 15·1 in Bristol, and 15·5 in Blackburn. The rates in the other towns ranged upwards to 25·7 in Salford, 27·9 in Birkenhead, 28·9 in Liverpool, and 36·8 in Norwich. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had declined from 877 to 718 in the preceding three weeks, rose again last week to 805; they included 606 from diarrhœa, 52 from whooping-cough, 49 from measles, 40 from "fever" (principally enteric), 32 from scarlet fever, 26 from diphtheria, and not one from small-pox. The lowest death-rates from these zymotic diseases were recorded last week in Plymouth, Halifax, and Huddersfield; and the highest in Salford, Leicester, and Norwich. The mortality from diarrhœa showed an increase, the largest excess being recorded in Birkenhead, Leicester, Liverpool, and Norwich. Measles caused the highest death-rates in Preston; scarlet fever in Salford; whooping-cough in Preston and Sunderland; and "fever" in Preston, Portsmouth, and Cardiff. Small-pox caused no death either in London and its outer ring or in any of the twenty-seven large provincial towns. No small-pox patients remained under treatment in the metropolitan asylum hospitals at the end of last week, the number on the preceding two Saturdays having been 8 and 5 respectively. The deaths referred to diseases of the respiratory organs in London, which had been 148 and 150 in the preceding two weeks, were last week 151, and 38 below the corrected average. The causes of 89, or 2·6 per cent., of the 3400 deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Norwich, Leicester, Newcastle-upon-Tyne, and in four other smaller towns. The largest proportions of uncertified deaths were recorded in Liverpool, Sunderland, Huddersfield, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 18·8 and 17·4 per 1000 in the preceding two weeks, rose again to 17·9 in the week ending August 21st; this rate was 1·6 below the mean rate of the same week in the twenty-eight English towns. The rates in the Scotch towns ranged from 11·5 in Perth and 11·8 in Greenock to 20·5 in Glasgow and 32·1 in Paisley. The 441 deaths in the eight towns showed an increase of 11 upon the number in the previous week, and included 23 which were referred to diarrhœa, 22 to whooping-cough, 9 to measles, 8 to scarlet fever, 5 to diphtheria, 5 to "fever" (typhus, enteric, or simple), and not one to small-pox; in all, 72 deaths resulted from these principal zymotic diseases, against 77 and 63 in the preceding two weeks. These 72 deaths were equal to an annual rate of 2·9 per 1000, which was 1·7 below the rate from the same diseases in the

28 English towns. The deaths referred to diarrhœa, which had been 28 and 18 in the preceding two weeks, rose again last week to 23, of which 15 occurred in Glasgow, 4 in Paisley, and 3 in Edinburgh. The annual death-rate from diarrhœa in these Scotch towns last week averaged only 0·9 per 1000, whereas the mean rate from the same cause in the twenty-eight English towns was 3·5. The 22 fatal cases of whooping-cough exceeded by one the number in the previous week, and included 18 in Glasgow. The 9 deaths from measles showed a further increase upon the numbers in the preceding two weeks, and included 4 in Glasgow, 2 in Edinburgh, and 2 in Leith. The 8 deaths from scarlet fever showed a decline of 4 from the number in the preceding week; 7 occurred in Glasgow. Two of the 5 fatal cases of diphtheria were recorded in Edinburgh, and 3 deaths from fever occurred in Glasgow. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 60 and 71 in the preceding two weeks, declined last week to 62, but exceeded by 11 the low number in the corresponding week of last year. The causes of 75, or 17 per cent., of the deaths in the eight towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had increased from 17·3 to 20·8 per 1000 in the preceding three weeks, further rose to 21·9 in the week ending Aug. 21st. During the first seven weeks of the current quarter the death-rate in the city averaged 20·2 ; the mean rate during the same period was 20·2 in London and 18·4 in Edinburgh. The 148 deaths in Dublin last week showed an increase of 7 upon the number in the previous week, and included 9 which were referred to diarrhœa, 5 to "fever," 4 to scarlet fever, 1 to whooping-cough, 1 to measles, 1 to diphtheria, and not one to small-pox. These 21 deaths from the principal zymotic diseases considerably exceeded the number returned in any recent week, and were equal to an annual rate of 3·1 per 1000, the rate from the same diseases being 3·8 in London and 1·8 in Edinburgh. The fatal cases of diarrhœa, which had been 2 and 4 in the preceding two weeks, further rose to 9 last week. The deaths referred to "fever" were 5, against 2 in each of the previous two weeks. The 4 fatal cases of scarlet-fever exceeded by 3 the number in the preceding week. Seven inquest cases and 3 deaths from violence were registered; and 38, or more than one-fourth of the deaths, were recorded in public institutions. The deaths of infants corresponded with those in the previous week, while those of elderly persons showed a decline. The causes of 18, or more than 12 per cent., of the deaths registered during the week were not certified.

THE SERVICES.

IN accordance with the decision to strengthen the medical department of the Upper Burmah Field Force, Surgeon-Major G. C. Roy, and Surgeons R. D. Murray, G. M. Dixon and W. Deane, are already ordered thither.

The services of Surgeon-Major Aylmer Hayes, Medical Staff, have been placed at the disposal of the Egyptian Government for duty with the Egyptian Army. Surgeon-Major Hayes proceeds at once.

Surgeon-Major J. F. Beattie, Medical Staff, now serving in the London district, has been ordered to proceed to Netley and assume the duties of Assistant-Professor of Medicine at the Army Medical School, Royal Victoria Hospital.

ADMIRALTY.—The following appointments have been made:—Surgeons George H. Milne, Alfred E. Weightman, James W. O. Underhill, Charles H. Upham, Frederick J. Burns, Alfred T. Rimmell, Daniel Patrick M'Nabb, James France, Charles Strickland, John Menary, Walter G. Axford, Walter C. Spiller, George T. Broatch, William Bett, Henry W. Rickards, Frederick A. Brise, and John W. Slaughter, to the *Duke of Wellington*, additional, for Haslar Hospital.

THE epidemic of fever which has existed for several weeks at Hare Island, off the coast of Cork, near Skibbereen, still continues, fresh cases being reported from the island and from the mainland close by.

"Audi alteram partem."

THE HOSPITAL FOR WOMEN, LIVERPOOL.

To the Editor of THE LANCET.

SIR,—As the Consulting Medical Officer to the Hospital for Women, Shaw-street, Liverpool, and as one of the unwilling witnesses subpœnaed by the plaintiff in the case of Casey *v.* Imlach, may I ask you to give insertion to the following statement, which I think is due to my professional brethren and to myself, of what my action had been in regard to the surgical practice of that hospital, especially during the six months immediately prior to the trial.

I had during the autumn of last year come to be aware, although I had not actually been present at many of these spaying operations, that they were being performed with increasing frequency, and when the Hospital Medical Report for the year 1885 appeared on Jan. 28th of this year I made a careful analysis of its contents, comparing it with the Report for 1884, and was dismayed at the record of the year's work. I thereupon, on Feb. 3rd, took upon myself the responsibility of writing a letter to the committee of the hospital on the subject, stating the bare facts that, according to the Medical Report for the year 1884, there were in that year thirty-one women completely spayed; while, according to the Report for the year 1885, the number of complete spayings had risen to ninety-six. At the same time I called their attention to this enormous increase in these operations, and stated that, as far as I knew, there were only four real consultations prior to operation in the whole number of 169 abdominal sections, although Law 39 says: "No operation of a dangerous character shall be performed in the hospital without a consultation between one of the medical officers for in-patients, or one of the consulting medical officers [there is but one] and the operator." I then went on to say: "That these operations are occasionally necessary, and are a valuable addition to the resources of scientific surgery, every surgeon will freely admit; but considering the very important ethical questions involved in such extremely delicate matters, it is but natural and right that the profession, as a body ever jealous of its honour, should view with anxious watchfulness any appearance of these operations being performed without (1) all possible precautions against errors of diagnosis and prognosis; (2) without proved necessity; (3) without clear and full information of the exact nature and necessary consequences of such operation having been previously given to the patient and her immediate relatives. It has come to my knowledge of late that many members of the profession in this city think they have reason to believe that in the Hospital for Women such necessary precautions have not always been taken; such necessary information as to the nature and consequences of the operation has not always been previously given to the patient and her immediate relatives; and, indeed, that these operations have, in some instances, been performed without due proof of their necessity." I then called attention to the cases of hæmatocele and hæmatosalpinx, in which this operation of removal of the uterine appendages had been performed, and of the inadmissibility of which operation in this class of cases I expressed my decided opinion, on the ground of the almost uniformly successful result of the generally recognised treatment by absolute and prolonged rest, with or without the addition of very simple and well-known medical treatment. So successful has this treatment hitherto been, not only with all those leaders of medical opinion who have written on this subject during the last twenty years, but with ordinary practitioners of standing with whom one comes into contact in daily professional work, that it is quite exceptional to find one of these latter who can remember a fatal case. To say the least of it, judging by the Hospital Medical Report for the year 1885, removal of the uterine appendages for hæmatocele and hæmatosalpinx has not been a successful practice, for out of nine cases operated on there were three deaths, a mortality of 33 per cent. It would appear as if the disciples of modern abdominal surgery had ceased to believe in the recuperative powers of nature, except as a consequence of their own operations.

The immediate consequences of this letter of Feb. 3rd to the committee were: first, that on the day following (Feb. 4th), at one of the largest meetings of members ever held in the Liverpool Medical Institution, it was unanimously resolved on my proposal to appoint a select committee of the leading members "to consider the grave questions of practice and ethics involved in the performance, in greatly increasing numbers, of these operations at the Women's Hospital, Shaw-street." (Being from home, I have not at hand the exact wording of the resolution, but what I have written is practically the substance of it.) The committee appointed at the same meeting, and without challenge, consisted of the following members: the president (Dr. Nevins), Dr. Cameron, Dr. Waters, Mr. Bickersteth, Mr. Mitchell Banks, Dr. J. H. Wilson, Dr. Macfie Campbell, and Dr. Alexander. Shortly after this, the committee of the hospital called upon their acting medical officers to report on every case of abdominal section during the year 1885, and their medical board to report as fully as possible on each case, with the condition of each patient up to the time of reporting; these reports to be sent into the Hospital Committee, who will transmit the same to the Medical Institution Committee for investigation and report. It will be readily understood how these reports, especially the following up the patients to their homes, many of them in the meantime having removed, and some more than once, have involved a great amount of time and trouble; but after several long and unavoidable delays, the report of the Medical Institution Committee will not now, it is expected, be very long delayed.

The trial Casey *v.* Imlach was an extremely unpleasant episode in this altogether unpleasant business, and not the least so to those who, like myself, were forced to appear in the disagreeable position of witnesses for the plaintiff, a person whom I had never seen, and about whose case I knew nothing until I heard her counsel make his opening speech. Holding the opinions I did as regards these operations, I can imagine no more unenviable position to be in; but it is a great consolation to know that you have written favourably of my evidence.—I am, Sir, yours truly,

August 23rd, 1886. THOMAS F. GRIMSDALE.

INTRA-PERITONEAL HÆMATOCELE.

To the Editor of THE LANCET.

SIR,—The difficulty in assenting to Mr. Lawson Tait's proposition, "that intra-peritoneal hæmatocele is fatal in 95 per cent. of the cases," does not seem to be removed by his letter in your current number. Take the cases where, during a menstrual period (the preceding period having occurred as usual), a patient, not rarely while making some violent effort, is suddenly seized with severe pain in the lower part of the abdomen, fainting, perhaps vomiting, and becomes markedly anæmic. These symptoms are often associated with temporary cessation of the menstrual discharge that was in progress, and its reappearance in a few hours. The next day a tumour is felt in the situation of Douglas's pouch, depressing the posterior fornix and pushing the uterus forwards. Sometimes the tumour is large enough to be felt through the abdominal wall above the pubes. Such cases are usually considered to be due to regurgitation of menstrual blood along the Fallopian tubes into the peritoneum. It is certain that a large proportion of cases with the train of symptoms and physical signs described recover completely. But for that very reason Mr. Lawson Tait cannot regard them as intra-peritoneal hæmatoceles.

I am, Sir, your obedient servant,

ARTHUR H. N. LEWERS, M.D. Lond.

Wimpole-st., Cavendish-square, Aug. 23rd, 1886.

THE CHOLERA EPIDEMIC IN VENICE.

To the Editor of THE LANCET.

SIR,—I beg to point out a peculiar feature in the "cholera epidemic" in Venice. It is essentially a poor man's disease. The well-to-do are free from it, with rare exceptions. Not very long ago I asked a gentleman, who from his position was most competent to speak on the subject, how many well-to-do people he had known to have died of the disease. He could not get beyond four, and one of these, to my knowledge, was a very doubtful case. When soup-kitchens and a cheap supply of food were set on foot the cases rapidly diminished. This may also have been due to the absolute prohibition of the sale of shell-fish and crustaceans, which came into force at the same time; and also to special precautions being taken to prevent the sale of bad fish and vegetables. The quantities of these seized and destroyed are simply incredible. I was told a few days ago of a man who, convalescing from double pneumonia, chose to eat two "folpe" (octopi). He was seized by cramps and vomiting, and of course was supposed to have cholera. Quarantines and "observations" go on as usual, trade suffers, and half-starved workmen and their wives and children are ready victims to attacks which, in the case of well-nourished individuals, would only require a little rest and mild treatment. The lower classes in Italy are, as a rule, sober; but they have a habit of over-eating themselves on certain occasions, and then they suffer severely. A great feast day was always followed by an increase in the number of cases. I have not heard of any case in an hotel here, but have seen one case of catarrh from exposure to cold, where the severity of the symptoms might have given rise to suspicion. Appropriate treatment soon effected a cure. I cannot see any reason why tourists should avoid Venice, if they will only take reasonable care of themselves. Very many of them, already run down by over-work, work harder still at sight-seeing, and suffer more or less from long railway journeys with irregular meals. The only wonder is that more of them do not get ill. A good deal might be said as to why so much is made of this epidemic, but it would not be appropriate in your columns.—I am, Sir, yours faithfully,

J. A. MENZIES, M.D.

Palazzo Banco Veneta, Venice, August 15th, 1886.

THE INCUBATION PERIOD OF DIPHTHERIA.

To the Editor of THE LANCET.

SIR,—The extreme importance of the above must be my apology for wishing to intrude these few lines into your valuable space.

When house-physician at King's College Hospital last winter, it happened that we were able, in two particular cases of diphtheria, to fix the exact period of incubation. At 10 P.M., on November 8th, the house-surgeon performed tracheotomy on a case of diphtheria. The operation, being a difficult one, took a considerable time. On the evening of November 10th, the house-surgeon himself complained of sore-throat, which was followed next day by the appearance of membrane. The incubation period here being a little under forty-eight hours. On Nov. 15th, some jelly which the house-surgeon had begun to eat, but had not finished, was removed to the kitchen at the end of the ward, and between 1 and 2 P.M. one of the ward maids partook of some with the same spoon as the house-surgeon had used. In the afternoon of November 17th she was attacked with sore-throat, which was followed by membrane. Here the incubation period was a little over forty-eight hours.

I am, Sir, yours obediently,

PERCY G. LEWIS, M.R.C.S.,
Associate of Kings' College.

August 17th, 1886.

DIRECT REPRESENTATION OF THE PROFESSION.

To the Editor of THE LANCET.

SIR,—The medical journals are quite right in naming me as a candidate for the direct representation of the profession in the General Medical Council, and when the proper time arrives I shall issue my address. In the meantime I trust the general practitioners will stand fast, and hold firm to the determination not to support any candidate who is not in general practice.—I am, Sir, yours truly,

EDWIN MORRIS,
General Practitioner of forty-five years' standing.

Spalding, August 23rd, 1886.

HULL HOSPITAL SUNDAY MOVEMENT.—The annual report of the general committee of this movement shows that the collections last year realised £738, and after the payment of expenses £554 were given to the Royal Infirmary, £20 to the Hull Dispensary, £66 to the Children's Hospital, and £23 to other institutions, leaving a small balance. It was resolved to fix Oct. 31st for the next collection.

CASTLEBAR LUNATIC ASYLUM.

AT a meeting last week of the governors of this asylum, Dr. Finegan, resident medical superintendent, stated that that was the last meeting he could attend, in consequence of having been appointed to the charge of the Mullingar District Lunatic Asylum. Before leaving he pointed out as objectionable the practice adopted by the coroner of holding inquests in every case of death which took place in the asylum. This is a source of considerable inconvenience to the officials, and should only be carried out when a sudden death takes place, which is the usual practice in lunatic asylums, and the governors intend drawing the attention of the coroner to the subject. The Board unanimously adopted the following resolution:—"It having been notified to the Board by the Lord-Lieutenant that Dr. Arthur Finegan has been transferred to Mullingar District Asylum, the Board wish to record their satisfaction at the manner in which Dr. Finegan discharged his duties during the time he acted as resident medical superintendent, from July 1st, 1885. He has conducted the work of the institution with much efficiency, and has given every attention to the afflicted inmates who have been under his care."

THE LATE DR. JOSEPH LALOR.

This gentleman, who recently resigned the post of resident medical superintendent to the Richmond Lunatic Asylum, Dublin, died at Sligo on the 17th inst., aged seventy-five years. Previously to his appointment at the Richmond he acted as resident physician to Kilkenny District Lunatic Asylum. Dr. Lalor was a graduate in medicine of Glasgow University, and an ex-president of the Association of Medical Officers of Asylums and Hospitals for the Insane. He published some papers on Dysentery and Fever, and was a contributor to the *Psychological Journal*, &c. He was a very efficient superintendent, and under his care and management the Richmond Lunatic Asylum has become a model institution of its kind.

MEDICAL MAGISTRATES.

Dr. Ryan, of Emly House, Tipperary, who was lately appointed to the Commission of the Peace, served through the Franco-Prussian War in the Anglo-American Ambulance. Dr. Charles Edward Crean, of Windsor Villa, Ballyhaunis, has been appointed to the Commission of the Peace for co. Mayo.

LONGEVITY IN IRELAND.

During the past quarter, among the deaths registered were the following at very advanced ages—viz.: One at 101, one at 102, two at 103, one at 104, and one at 112 years respectively.

Dr. Hugh Brosnan, of Castleisland, in the county of Kerry, has been committed for trial at the next assizes for alleged complicity in a Whiteboy offence.

Dublin, Aug. 24th.

BELFAST.

(From our own Correspondent.)

BELFAST ROYAL HOSPITAL.

FROM the report read at the quarterly meeting of this charity on Monday we gather that during the past quarter there were 502 intern patients, while during the same time there were treated as extern patients 3580, making the large total of 3950 cases. The total receipts from all sources to the end of July amount to £7500 18*s.* 4*d.*, but the ordinary income has not kept up with the expenditure, for when the accounts due by the hospital up to the end of July are paid there will be a deficiency amounting to £777 11*s.* 9*d.*—a deplorable state of things considering the pressure and special demands which have of late been made upon the institution in connexion with railway accidents and local disturbances. The urgency of the claims has been such that many new beds have had to be fitted up, and great expenditure was needed for the surgical treatment of the cases, and while all this has been going on there has been a diminution of support. Of the 3580 extern cases in the last quarter, the altogether unprecedented number of 3200 have been surgical, and it is estimated that the cases treated at the hospital in connexion with the late unfortunate riots have cost the board of management between £700 and £800. During last quarter Dr. Calwell (formerly house-surgeon) was appointed house-physician, while Dr. Shuldham Dunlop was elected to the post vacated by the former. The two retiring members of the medical staff, Dr. Whitla and Dr. O'Neill, were unanimously re-elected. The report also states that at one of the meetings of the board they unanimously adopted the following resolution, and forwarded a copy of the same to the members of Dr. Mac Cormac's family:—"That the board record their high appreciation of the character and services of the late Dr. Mac Cormac, who for many years acted as one of the physicians of the hospital, and up to the time of his death was one of the consulting staff. They bear willing testimony to his great ability and conscientiousness, and desire to express their sympathy with the members of his family in the great bereavement they have experienced."

ELECTION OF SENATOR OF THE ROYAL UNIVERSITY.

A vacancy having recently occurred in connexion with the Senate of the Royal University through the death of Dr. Curtis, an active canvass is taking place for the position, and a correspondence has been going on in one of the local papers. There are two local candidates, both members of the medical profession—Dr. W. K. McMordie, physician to the Samaritan Hospital, and Dr. Whitla, physician to the Royal Hospital. Mr. Farrelly of Dublin, and it is said Captain Fitzgerald of Cork, are also candidates. Dr. McMordie has issued an address for the post of elected representative to the General Medical Council. I hear of no other local candidate.

Belfast, Aug. 24th.

PARIS.

(From our own Correspondent.)

THE ACTION OF THE AIR AT CERTAIN ALTITUDES ON PULMONARY HÆMORRHAGE.

WITH reference to your editorial note of the 5th inst., on the *Rationale* of the High Altitude Treatment of Phthisis, a paper lately communicated to the Société Française d'Hygiène, by Dr. Deligny, on the Action of the Air at certain Altitudes on Pulmonary Hæmorrhage, may be of some interest. The paper began by citing Professor Lombard, of Geneva, who had brought to notice the fact that, in phthisical subjects, hæmorrhage is rarer at a certain altitude than on the plains. The same fact was noticed by Brehmer, Weber, and Kuchenmeister; and Prof. Jaccoud, in his clinical lectures, has laid down as a principle that hæmoptysis, or a tendency to it, is favourably influenced by occupying certain altitudes, and that they are in these cases of some utility. Dr. Deligny goes on to explain the action of mountain air as follows:—"From a height of 2000 feet to 3000 feet, the higher one ascends the more the air of the mountains modifies the functions of the circulation and of respiration, which is the consequence of the diminution of atmospheric pressure, the lowering of the temperature, and also of other factors which are of less importance. Upon the side of the respiration there is an augmentation of the pulmonary capacity, an enlargement of the thoracic cavity, and an acceleration of the expiratory movements. The respiration is more ample, the inspirations are more profound; in short, the entire lungs fully perform their function. This circumstance has been adduced to explain the immunity from phthisis which inhabitants of mountains enjoy. On the side of the circulation there is, as a first phenomenon, an acceleration of the beats of the heart, followed by an afflux of blood to the periphery, and turgescence of the cutaneous capillaries, indicated by a more intense colouration of the mucous membranes, as may be seen in those of the mouth and of the tongue. From this cutaneous congestion and the afflux of blood to the periphery result, according to Professor Jaccoud, an anæmia of the viscera, which, however, is relative and slight, and is marked by symptoms rather favourable than otherwise; the cerebro-spinal functions are more active, more easily performed;

the respiration is easier; the power of locomotion is increased. The lungs participate in this anæmia of the viscera, and the circulation of the organ is thus relieved, the tendency to pulmonary congestion is less, and even the pre-existing congestion disappears. This action of the air of high altitudes on the circulation would explain its anti-hæmorrhagic effects. It has been asserted that a sojourn in a brisk and cold air facilitates pulmonary congestion. This is perfectly true for the cold and damp air of the plains, but the contrary is observed for altitudes, the air of which is cold and brisk, but remarkably dry. To ensure the anti-hæmorrhagic action of the air of great altitudes certain conditions are necessary before any appreciable effects can be produced. In the first place the altitude appropriate to individual cases must be taken into consideration. Professor Lombard divides mountain climates into two categories—1. Climates that are more sedative than tonic, which may be found at an altitude of from 2000 to 3000 feet. 2. Those that are more tonic than sedative, at an altitude above 3000 feet. The next condition necessary is acclimatisation, the period of which should depend on circumstances, and invalids should never be removed direct from the plains to the higher regions, but this should be done by stages before they proceed to the highest point prescribed above in order to avoid the risks already referred to. Acclimatisation is therefore an important element in the application of climatic therapeutics of altitudes. This opinion is in accord with that expressed by Professor Jaccoud. But while mountain air is favourable to pulmonary hæmorrhage, it would be injurious in hæmorrhages from the intestines, the stomach, and the uterus.

A CURIOUS CASE OF CATALEPSY.

A curious case of lethargy in a female patient at the Salpêtrière is just now causing great sensation in Paris. The patient is forty-seven years of age, and, without any apparent cause, fell into a profound sleep, from which she awoke after eighteen days. During this sleep the respiration of the patient was very irregular. Insensibility was almost complete; one could thrust needles into her skin without provoking the slightest manifestation of pain. She was nourished with milk, bouillon, and eggs. Eudoxie Hedouin, which is the patient's name, is one of the oldest *pensionnaires* of the Salpêtrière, where she was admitted in 1862 with hemiplegia of the left side, and since that time she has never walked. She is of extraordinary *embonpoint*, and at one time weighed 140 kilogrammes, or nearly 309 lb. avoirdupois. On awaking from her sleep last week she was seized with a violent nervous trembling, which was accompanied by burstings of hysterical laughter lasting about ten minutes. She then opened her eyes, and said "Bon jour" to someone whom she took for her mother, and never uttered another word on the first day. At the visit on Friday last she was offered an empty glass, making her believe that it was filled with champagne. At three different times, in putting the glass to her lips, she imagined that she had been drinking from the glass, and then manifested all the symptoms of inebriation; but on offering her a piece of aloes and trying to persuade her that it was sugar, she made a significant grimace on tasting it. During her sleep, Dr. Voisin, in whose ward she is, performed on her a most curious experiment. Without uttering a word in presence of his pupils, the doctor placed in the first instance on the chest of the patient a small packet containing tartar emetic, where he left it for a few minutes, and then replaced it by another packet in which there was nothing. Then, addressing his audience, he said in a loud voice: "You will see, gentlemen, the effect which the tartar emetic is going produce by simply placing it on the epidermis of the patient. In five minutes nausea and vomiting will appear." Accordingly, at the expiration of the time, the predictions of the doctor were realised. It must, then, be concluded that the patient, in spite of her sleep, heard what the doctor said. Since she has awakened she does not seem to be quite conscious, but drinks, eats, and sleeps as at ordinary times.

M. CHEVREUL.

The popular fêtes that are being organised to celebrate the hundredth birthday of M. Chevreul at the end of this month, as already reported in THE LANCET, are assuming more of a national character, as the official authorities and the public are vying with each other to do honour to the illustrious centenarian. On August 31st a grand banquet is to be given at the Hôtel de Ville by public subscription, after which there will be a grand military procession, with lighted torches and music, which will pass through the principal streets of Paris. On the morning of September 1st the inauguration of the buildings annexed to the Museum of Natural History will take place, under the presidency of the Minister of Public Instruction, when a statue of the champion of the day will be unveiled, and a eulogy will be pronounced by one of his colleagues, probably M. Frémy, the present director of the Museum. On the same day will be also opened at the Museum an exhibition recalling the discoveries of M. Chevreul, and their applications to industry. On Monday, the 30th inst., a special representation is to be given in his honour at the new Opera House, for which he has received an express invitation, which has been accepted by him. I learn that he has never been to the new Opera, and indeed he has never entered a theatre for the last twenty years. The presence of such a man under such circumstances is rather unique in the annals of history, and it is to be hoped that the venerable chemist will possess sufficient vitality to be able to resist the excitement caused by the demonstrations made in his favour.

Paris, Aug. 25th.

EGYPT.

(From our own Correspondent.)

GREAT FAIR AT TANTAH.

THIS festival, held every August in honour of a Moslem saint of great renown who lived in the thirteenth century is now drawing to a close, after nine days and nights of superstitious reverence and dissipation and revelry. Arabi's rebellion and the cholera epidemic have prevented this fair from taking place since 1881, though an impromptu gathering of large dimensions was brought together last year. This year the villagers, who are the chief visitors, flocked in great numbers to say a few prayers at the tomb of the saint, buy and sell cattle, and pass the rest of their time in pleasure, with little restraint. The numbers are said to have risen this year to 500,000, and this would seem possible, for there have been 8000 native marquees, each sheltering about fifty people, besides all the small tents of the fair and the men who sleep and live in the streets. Tantah has a population of about 60,000, and a daily mortality of five or six. It is remarkable that so great an influx of natives has not raised the death-rate. This is partly due to the tents being pitched on open ground, and to the measures enforced recently by the sanitary department. A native sanitary inspector and four assistants had divided the town and pilgrims into sections. They paid them constant visits, established latrines where necessary, cleaned the mosques, and attended generally to the conservancy arrangements. The feeding of this large mass of men is of no trouble to the State, for each family brings its own commissariat on camel or donkey back, but a brisk trade was being carried on in "popcorn" and sweetmeats, for which the fair is famous. Hasheesh (cannabis indica) tents were crowded with solemn, rather unhappy-looking devotees, who were cautiously furnished with the forbidden drug by the attendants with many mysterious nods and winks. No smoker took more than one inhalation, and then passed the pipe on to his friends, and afterwards to the poorer members of the fraternity. Most men can take fifty or more inhalations during an evening, and are then prepared to thoroughly enjoy any wit or punster's efforts, or are wafted into the sensual dreamland common in Egypt. Much native music and singing was to be heard in other tents, and the facial grimaces on the part of the men and the wonderful movement of the women's thoracic and abdominal muscles, which is usually called dancing, were very popular. Besides the absence of Europeans and the effendi class of natives, another remarkable feature is the presence of veiled women sitting with men in the cafés.

THE ONLY ARABIC MEDICAL PAPER.

Egypt boasts of only one medical journal, *El Shifaa* (The Cure), which was started last February, and so far has been a great success. It is published monthly, the price being 1s. 4d., at the office of a native scientific paper, and is moderate.

is edited by a Syrian in Cairo—Dr. Shemeil—and Dr. Milton. At its start the sanitary department offered to buy 120 copies and distribute them among their officials; but as it was at once found that the native doctors brought its circulation up to 400, the offer was declined. It already pays its way, and will, it is to be hoped, be of incalculable benefit to provincial doctors possessing no modern medical literature. The chief contributors are natives of Egypt and Syria, and Dr. Milton, besides publishing many hospital cases, is now writing on the Treatment of Wounds. Dr. Kartulis of Alexandria has recently contributed a paper on the Giant Amœbæ, which he maintains are specific of dysentery.

ENGLISH TROOPS IN EGYPT.

Malaria is almost unknown in Cairo, but cases occasionally occur at this time of the year, when the Nile is rising and inundating the fields. The Welsh regiment, which came here from Mauritius and the Cape of Good Hope, has suffered much lately, both from a paroxysmal fever of malarious type and from a continued fever, which is uninfluenced by quinine. The regiment has been moved from the river bank to barracks on the edge of the desert.

Cairo, August 14th.

TURKISH HOSPITALS AT CONSTANTINOPLE.

FROM A CORRESPONDENT.

(*Concluded from page 392.*)

THE Constantinople correspondent of the *Journal des Débats*, whose interesting description of the foreign hospitals in the Turkish capital I brought before your readers the other day, expresses himself as being very agreeably surprised at finding the Turkish hospitals themselves admirably managed and scrupulously clean. The only exception is in regard to the Bimar Hané, or hospital for the insane. This asylum is at Scutari, the building having been used as barracks for the soldiers of the Sultan Mahmoud, but converted into a lunatic asylum fifty-five years ago by Dr. Mongeri, who was the first physician in Turkey to substitute kind treatment for the brutality of which the insane were formerly the victims. The establishment of Bimar Hané is, however, very deficient in comfort, there being only two dormitories, containing about 150 beds, in which the unfortunate patients are huddled together, many of them having to sleep two in a bed. They have nothing in the way of clothing but a shirt, a pair of drawers, and a cotton cap, and there is no covered courtyard for them to take exercise in. They are supposed to have two meals a day, consisting of vegetable soup and pilaff, but the correspondent of the *Débats* describes the food as insufficient in quantity and poor in quality. There are few dangerous lunatics among the men, and the listlessness of mind and body which is always the chief characteristic of the Turk seems in this asylum to reach its maximum of intensity. There are, however, many cases of hysterical insanity among the women, though the negresses at Bimar Hané, who are rather numerous, seem to be immersed in gloomy reflections, as if longing for the burning sands of their desert. There are at the present time 450 men and 170 women, including 70 Christians, in the asylum, and the annual cost of this establishment is £11,600, of which a third is supposed to be contributed by the Government. This subsidy is, however, paid with Turkish punctuality, and the remainder is made up by grants from the different provinces, in accordance with the number of insane from each under treatment there. There are three doctors attached to the asylum, receiving salaries, one of £20, the two others of £7 a month, while there are 50 keepers and attendants, whose pay is only 16*s.* a month. The mortality is about 14 per cent., and the correspondent of the *Débats* adds that when he visited the asylum there were no fewer than 70 patients in the infirmary suffering from intestinal complaints.

The Gourabat Hospital, also called the Charity Hospital, is in striking contrast to the above; and it would be difficult to find a better managed establishment than this, which is under the charge of Ahmet Pasha, who followed his medical studies at Constantinople, and is thoroughly conversant with the progress of modern science. This hospital, situated at Stamboul, was built about forty years ago by the Sultana-Validé, mother of Abdul-Aziz, who took the greatest interest in it. A set of scales is shown to visitors in the pharmacy, which have a piece of string attached to them by the sultana, who removed a small silver chain, saying that "she would not have anything showy in the place." The Gourabat Hospital is a large quadrilateral building of only one storey, around the inside of which is a covered gallery with a garden in the centre. On to this gallery open 22 dormitories, each nearly 40 ft. square by 16 ft. high, well ventilated, and containing altogether 300 beds. Each bedstead is of iron, with curtains, two mattresses (one stuffed with maize and the other with wool), two pillows, and two blankets. Only male patients are received, and there is no restriction as to the nature of their complaint. The staff consists of the chief physician, Ahmet Pasha, three house-doctors, four surgeons, a pharmacist, and 51 nurses and attendants, the chief physician having the rank of brigadier-general; the others of colonel, with pay in proportion. The income of the hospital is about £12,000, derived from the rent of house property belonging to the foundation, and the expenses are about £7000, exclusive of the pay of the staff. Of the 4738 patients who passed through the hospital, 473 died, the rate of mortality being about 10 per cent. Out of the number of deaths, 125 were from fever, 113 from diseases of the chest and lungs, 102 from abdominal complaints, 76 from external or cutaneous complaints, and 57 from diseases of the brain. More than 10,000 gratuitous consultations are given in the Gourabat Hospital every year; and the correspondent of the *Débats* was much struck by the respectful attitude of the patients towards the staff, and by the absolute silence which prevailed throughout the dormitories.

The Hasseki Hospital is for females, and contains 120 beds, all of which are gratuitous except six, for which a charge of rather less than 2*s.* a day is made. The Hasseki Hospital is also at Stamboul, a magnificent konak, or villa, having been purchased two years ago for about £60,000. There is a ward with ten beds for women about to be confined, one of six beds for ophthalmic complaints, two of six beds each for children, while the rest are for general complaints. Three doctors and 25 nurses and attendants are attached to this hospital, the annual expenditure of which is about £4000, contributed by the municipality. The number of patients received last year was 596, of whom 111 died. There are eight military hospitals, with 3000 beds, the most important being the Naval and Seraskeriat Hospitals. The hospital of the navy is a magnificent building, situated upon the Golden Horn, with two storeys each, having thirty windows upon the façade. It contains 500 beds, distributed over 25 wards, the mortality being only 2 per cent., as the hospital only keeps the patients who can be cured, all the incurable cases being discharged. The management of the hospital is excellent, there being five doctors belonging to the different religions, besides 100 attendants all taken from the navy. The wards and beds are of irreproachable cleanliness, and a variety of naval engravings and models of ships are displayed upon the walls, in order to amuse the patients. The kitchens and pharmacy are beautifully clean, and no fewer than 7889 persons passed through this hospital last year, all the expense being borne by the Minister of Marine.

The Seraskeriat Hospital is a building of two storeys, containing 160 beds distributed over five wards, one of which has ten beds for officers. There are ten army doctors attached to it, one of whom, Mikaël Bey, ranks as a colonel. As at the Naval Hospital, the cleanliness and general management leave nothing to be desired, and the correspondent of the *Débats* can vouch for the fact that the food supplied is most appetising. The rate of mortality is very low, and as the Seraskeriat Hospital is the central one, its pharmacy is of great importance, more than 600 prescriptions being made up daily. Last of all comes the Miskin Hané, or Lepers' Hospital, at Scutari, which was founded by the Sultan Selim, and for a long time received a Government subsidy of twenty piastres a month for each patient. This sum is now insufficient, and the hospital, to which Dr. Zambaco devotes so much attention, is dependent upon casual charity. The Miskin Hané is the centre of the vast cemetery in which so many million bodies have been interred, so that the lepers are literally enclosed within a living tomb. The hospital is a quadrilateral about 120 feet long, and with one storey. There are only twenty rooms for the twenty-seven patients, who drag out a wretched existence in the most abject misery, only relieved by the devotion of Dr. Zambaco, who believes that leprosy is not contagious, and who comes twice a week, handling the lepers with perfect impunity

MEDICAL NOTES IN PARLIAMENT.

Alleged Flogging at Hanwell.

IN the House of Commons on the 20th inst., Mr. Ritchie, in reply to Mr. Pickersgill, stated that his attention had been called to what, on the face of it, seemed to be the very cruel treatment of an inmate of the Hanwell Pauper Schools, and before deciding what course to adopt with reference to it he had thought it desirable to call for any explanation the drill instructor might have to offer upon the question, and he had also asked the guardians and managers of the school to favour him with any observations they had to make as to the statement that there was an unnecessary amount of flogging at the school. Mr. Ritchie added that the rules and regulations as to corporal punishment at these schools are very stringent, and under no circumstances whatever does it fall within the duty of a drill instructor to inflict corporal punishment.

The River Lea Committee.

Sir Charles Russell moved that the Select Committee of the last Parliament to inquire into and report upon the condition of the River Lea, and to make such recommendations as may appear necessary, be reappointed. The Chancellor of the Exchequer said that the Government would facilitate the reappointment of the committee on the earliest possible day next session, it not being possible that real progress could be made with the subject at the present time. Sir Charles Russell expressed his satisfaction with the statement, and did not press his motion, which was accordingly withdrawn.

Irish Lunatic Asylums.

A Bill to amend the law relating to private lunatic asylums in Ireland was brought in by Mr. W. Corbet, and read a first time.

Ventilation of the House.

On the 23rd inst., on the motion of Mr. Jackson, the Committee on the Ventilation of the House was reappointed.

Medical News.

BRITISH MEDICAL SERVICE.—The following is a list of candidates who were successful for appointments as Surgeons in the Medical Staff of H.M. Army at the competitive examination in London on Aug. 9th and following days:

Morgan, F. J.	3180	Gray, W. L.	2380
Hale, C. H.	3050	Salmon, L. E. A.	2370
Burnside, E. A.	2895	Holt, M. P.	2360
Poole, W. C.	2870	Stelli, D.	2360
Horrocks, W. H.	2830	Morgan, J. C.	2340
Raymond, G.	2765	Weir, C. J.	2330
Thurston, H. C.	2750	Hinde, A. B.	2325
Reilly, A. Y.	2690	Bullen, J. W.	2320
Scott, B. H.	2655	Inniss, B. J.	2310
Wade, G. A.	2655	Penton, E. H.	2310
Hore, H. St. G.	2650	Thacker, R. C.	2300
Watson, A. C.	2620	Pocock, H. J.	2290
Julian, D. K. A.	2610	Young, C. A.	2265
Corcoran, E.	2580	O'Brien, M.	2240
Cockerill, J. W.	2540	Hassard, E. M.	2235
McCullock, J. C.	2500	Hilliard, G.	2235
Macdonald, S.	2495	Murphy, W. N.	2200
Ritchie, J.	2490	Elliott, C. K.	2150
Gray, E. W.	2470	Clark, S. F.	2110
Minniece, J.	2460	Sinclair, F. C.	2090
Browne, E. G.	2380		

INDIAN MEDICAL SERVICE.—The following is a list of candidates for appointments in this Service who were successful at the competitive examination held at Burlington House on Aug. 9th and following days:—

Macnamara, R. P.	3165	Sellick, J. H.	2530
Pilgrim, H. W.	2970	Hare, H. C.	2490
Swinburne, J. McD.	2770	Clarkson, F. C.	2480
French, G. B.	2740	Castor, R. H.	2470
Thomson, F. W.	2735	Morris, H. M.	2470
Hall, G. C.	2730	Maidment, F. G.	2400
Henderson, S. H.	2715	Doyle, J. P.	2370
Green, C. R. M.	2710	Blancard, J. T.	2350
Dyson, J. E.	2650	Hall, E. A. W.	2340
Bensley, C. N.	2630	Scotland, D. W.	2340
Brown, E. H.	2620	Morwood, James, M.D.	2330
Grayfoot, B. B.	2570	Russell, A. R. P.	2315
Jordan, J. G.	2570		

Thirty seven candidates competed for twenty-five appointments. Thirty-three were reported qualified.

SOCIETY OF APOTHECARIES.—The following gentlemen passed their examination in the Science and Practice of Medicine, Surgery, and Midwifery, and received certificates to practise, on Thursday, the 19th inst.:—

Robinson, Abraham Hepworth, M.R.C.S., Manchester-road, Hodenwood, near Manchester.
Sankey, Julius Ivor, Portland-road, Notting-hill.

A DEMONSTRATION in aid of the funds of the Beckett Hospital and Dispensary, Barnsley, was held on the 22nd inst. The amount realised exceeded £62.

THE Emperor of Russia has sent 40,000 roubles to the Pasteur Institute, the total subscriptions to which now amount to £64,000.

AN inquest was held at Bath on the 23rd inst. on the body of a woman aged sixty-four, who died from shock to the nervous system caused by the sting of a wasp.

THE Caucasian Medical Society has awarded its annual prize of 100 roubles, given for the best original paper contributed to the Society during the year, to Dr. Neumann for a work on the Pendjeh Sore.

WOLVERHAMPTON EYE INFIRMARY.—Mr. Horsman, to whom Wolverhampton is indebted for its art gallery, has just given £4000 to cover the cost of providing and furnishing the in-patient department of the intended new eye infirmary. This makes the total sum already subscribed £9500 towards the £12,000 required for the erection and furnishing of the new building.

JAPANESE WATER-SUPPLY. — On the authorities making an examination of the wells of Nakamachi recently 777 out of 939 were found to be unfit for drinking purposes, and the analysis of many showed traces of sewage contamination. Such a condition of the water-supply leaves room for no surprise at the statement that cholera has taken root in many places in the country.

HUDDERSFIELD INFIRMARY.—Messrs. John Brooke and Son have intimated to the president of this institution their intention to subscribe £600 to the fund which is being raised for the erection of a new ward for children and other extensions of the infirmary. The sums already promised amount to £3350, which is nearly one-half the amount required.

PRESENTATION. — On the 12th inst. a testimonial was presented to Mr. W. H. Thornton, M.R.C.S., on behalf of the vicar, churchwardens, and parishioners of the parish of Holy Trinity, Margate, on his retirement from the office of churchwarden, which he has filled for the long period of thirty-two years. The testimonial took the form of a silver teakettle and lamp, the former bearing a suitable inscription.

WEYMOUTH SANATORIUM. — At the thirty-eighth annual meeting of the supporters of this institution on the 19th inst., it was reported that the number of in-patients under treatment during the year had been 208, and of out-patients 863, making totals of 2621 and 35,560 respectively since the opening of the institution in 1848. The financial condition of the sanatorium continues to be satisfactory.

DEATHS OF M. PASTEUR'S PATIENTS.—A little boy residing at Rawtenstall, in Yorkshire, died on the 20th inst. from hydrophobia, having been bitten about six weeks ago. Within nine days after the injuries had been received he was treated by M. Pasteur, during his ten days' residence in Paris receiving thirteen inoculations. At Ferrol and Reus a woman and a man have also died from the disease; the sufferers in both these cases, too, had undergone a course of treatment in Paris under M. Pasteur.

THE DISPOSAL OF THE BODIES OF PAUPERS.—At a meeting of the Spalding Board of Guardians on the 23rd inst., a motion to secure the abandonment of the practice of forwarding the bodies of persons who die in the workhouse, and who have no relatives, to hospitals or colleges for dissection, was introduced, and it is expected that at the next meeting of the Board the minute relating to it will be rescinded. This action has been taken in consequence of the body of a labourer who died in the workhouse apparently without friends, having been sent to the Cambridge School of Medicine. The relatives, indignant at such a disposal of the [illegible] aver that they would have buried it had ings moderate [illegible]e.

In connexion with the meeting of the British Association on Wednesday next, an Industrial Exhibition has already been opened, which, though limited to towns within a radius of fifteen miles, will, it is expected, be of an attractive character.

GELOSINE.—In the "Bulletins et Mémoires de la Société de Thérapeutique" (Paris, July 15th), M. Guérin published a communication on gelosine, a mucilaginous principle which he has extracted from the *gélose* of Gelidium corneum, an alga of Japan. It is an amorphous, uncrystallisable, colourless, non-azotised substance, closely resembling lichenine of the lichens and fucine of the algæ. It is also similar to the pectose of ripe fruits which determines alimentary vegetable jellies. Gelosine is dissolved in boiling water, of which it solidifies about 350 times its volume. To give an idea of this very great suspensive power, 250 grammes of gelosine immobilise 250 litres of water. On cooling, this solution is transformed into a fine transparent jelly, capable of assuming any shape and varying consistence. Therapeutically this jelly constitutes a valuable new excipient: salts, acids, powders, and extracts may be dissolved in it and dispensed in any desired form. The price of gelosine is so moderate that it may be used in hospital practice, and, when properly sterilised, it promises to be of use in the researches of micro-biologists. As the substance is inalterable, it may be melted indefinitely with very little loss.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

HORNE, THOMAS, L.R.C.S., L.R.C.P.Ed., has been appointed Medical Officer for the Stockton District and the Workhouse of the Stockton Union.

LITTLEWOOD, HARRY, F.R.C.S.Eng., has been appointed Resident Surgical Officer to the General Infirmary, Leeds, vice F. H. Mayo, resigned.

WHITE, ERNEST A., M.R.C.S., L.R.C.P.Lond., has been appointed Medical Officer for the Fifth District of the Leeds Union.

Births, Marriages, and Deaths.

BIRTHS.

CAPON.—On the 22nd inst., the wife of Herbert J. Capon, M.D., of a son.

FINLAY.—On the 21st inst., at Dalkey, co. Dublin, the wife of Surgeon-Major Finlay, Medical Staff, of a son.

GOLDSMITH.—On the 28th ult., at Sutna, Central India, the wife of Surgeon-Major S. J. Goldsmith, of a son.

JOHNSTON.—On the 15th inst., at Guisborough, Yorkshire, the wife of George F. Johnston, M.B., of a son.

MARRIAGES.

BARTON—LAURENCE.—On the 19th inst., at [illegible], Barton, M.D., of Market Rasen, to Harriet Bloomy Rebecca, daughter of the Rev. Perceval Laurence, Rector of [illegible].

PRICE—PAGE.—On the 24th inst., at [illegible], Alfred Parry Price, M.D., of [illegible], to Annie, daughter of J. Bentley Page, Esq., of [illegible].

THIELE—DIXON.—On the 15th inst., at [illegible], Herman Thiele, M.B., C.M., Surgeon [illegible], to Helen Isabel, eldest daughter of the late Thomas Dixon, of Walesby.

TOBIN—COSTELLO.—On the 17th inst., at St. Stephen's, Hampstead, John North-William-street, Dublin, [illegible], to Frances Mary, eldest daughter of Ja[illegible], A.M.S., to Fanny, daughter of [illegible], at St. John's Church, Chatham, Raheny, co. Dublin.

WHITCOMBE—BUSBRIDGE.—On the 18th inst., at St. Louis Frances Kate, South Kensington, Philip Percival Whitcombe, [illegible], to Church of St. Agatha, Blanche Beatrice, youngest daughter of George Busbridge (retired), The Lodge, West Malling, Kent.

DEATHS.

HAINS.—On the 22nd inst., at Bridge Town, Totnes, [illegible], Frost Palmer Hains, Surgeon, aged 66.

PASH.—On the 13th inst., at Eskbourn, Lauris-[illegible], Pash, M.A., M.B.Camb.

WILLIAMS.—On the 19th inst., at Mold, William [illegible], M.R.C.S., aged 68.

N.B.—*A fee of 5s. is charged for the Insertion of [illegible], Marriages, and [illegible].*

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

We cannot undertake to return MSS. not used.

HOMŒOPATHY.

An Old True Blue asks various questions about homœopathy.—1. What is homœopathy? That is a poser. There are probably not six homœopaths in England who would accept the principles of homœopathy laid down by Hahnemann. Dr. Kidd, who is the most popular leader of the sect, says there are two principles: *similia similibus curantur*, and *contraria contrariis curantur*.—2. There is no homœopathic university in England, nor, so far as we know, in Europe.—3. There is no legal homœopathic licensing body in England.—4. Homœopathy is not the best practice according to the best science of the day, but is a [illegible] erent religion. The medical profession does not consider it a fallacy.—5. [illegible] degree from a British university to practise homœopathy; but the law particularly forbids any excuse [illegible] body or other medical authority to refuse its qualification to a gentleman on the mere ground of his holding peculiar theories of medical practice.—6. There is nothing illegal in homœopathic dispensaries.

G.P.—The details of the case are hardly sufficiently numerous and precise to warrant us in offering an opinion upon it.

NAIL-SWALLOWING.

To the Editor of THE LANCET.

SIR,—If you consider the following worthy of insertion it may be of interest to some of your readers.

A. G——, a fine little fellow of four years of age, picked up a large brass-headed nail, two inches long, and commenced sucking it, when suddenly it slipped from his fingers down his throat. When I saw him, half an hour after, he was looking very pale and anxious, complaining of great weight in the stomach, and a feeling of sickness, which remained for three days, passing off and leaving the child, to all appearance, in perfect health. Four days after, just seven days from the time of the accident, the nail was voided, embedded in a hard mass of fæces. The treatment was from the first perfect rest, and the bowels confined with a mixture of two minims of solution of morphia and five minims of dilute sulphuric acid, every three hours.

I am, Sir, yours faithfully,

Colebrooke-row, City-road, N., August, 1886. J. W. SMYTH.

NEW POLISH MEDICAL JOURNAL.

THE *Przeglad Lekarski* states that the new Polish medical journal, *Wiadomosci Lekarski*—i.e., Medical Gazette—will be devoted chiefly to abstracts from foreign journals, including the Russian ones.

Mr. Ballamy.—Very shortly.

JEWS AND MEDICAL PRACTICE IN RUSSIA.

THE Russian Medical Department has been collecting statistics showing the number of Jews who are practising medicine, pharmacy, &c. It seems that in Odessa there are of such 99 doctors (including 6 women), 3 veterinary surgeons, 9 dentists, 35 midwives, 10 feldshers, 19 apothecaries, and 4 apothecaries' managers—altogether 178. It is feared that the authorities contemplate making an order limiting the proportion of Jews allowed to engage in civil practice, in the same way as those in the military medical service are limited to a tenth of the whole.

DEE.—We see no reason why our correspondent should put himself on his defence in the circumstances mentioned. The change of mind was on the other side. He fulfilled all his engagements, and may rest satisfied with the *mens conscia recti*.

Mr. G. R. Newcastle.—We cannot depart from our rule.

THE DRAINAGE AND SEWAGE DISPOSAL OF LONDON.

To the Editor of THE LANCET.

SIR,—To drain London thirty years ago was looked upon by the uninitiated who had never studied sanitation as a somewhat gigantic affair. Mr.—afterwards Sir Joseph—Bazalgette had been elected Road Surveyor to the Metropolitan Board of Works, and to him belongs the credit of carrying out the work—a work which all admit has been very well done, according to what London was at the time. The first mistake was that he did not foresee and comprehend what London was to be in after-time. The result has been the ever-increasing pollution of England's noblest river, and the accumulation of a mass of filth, defying all the wisdom of the Board of Works to know what to do with. Yet, the remedy is as certain as that the Board of Works do not understand it, or with intensified obstinacy will not see it. When our Belgian, Colonial, and Indian visitors recently inspected the sewage works at Crossness, they must surely have been astonished that the discharges of fifty square miles of a thickly-populated district had to be received nearly thirty feet below mean high-water mark, and then at enormous expense of machinery and coal had to be pumped the same height again to be discharged into the river, after being treated by chemical means to decompose and unfit it for agricultural use, when the same or less amount of money differently spent would have made it a valuble commercial commodity. Those gentlemen could not have been much impressed with the value of the engineering and chemical skill that could perpetrate such a blunder. London, however, will in time be brought to see that as one mistake often generates another to remedy or conceal the first, so the first palpable deficiency in the scheme of Sir Joseph Bazalgette will necessitate a change in both drainage and sewage disposal that will be more or less expensive to complete, according to the time wasted in having it done.

I am, Sir, your obedient servant,

Batoum Gardens, W., Aug. 22nd, 1886. W. HEMPSON DENHAM.

Mr. Samuel Constable.—We think the action of the chemist was uncalled for; but it is scarcely worth while for a medical man to hold a dispute with a chemist on such a question.

Mr. E. S. Pattison.—Gastein, Kissingen, and indeed the majority of the German baths treat the condition named.

"THE USE OF COCAINE IN CIRCUMCISION."

To the Editor of THE LANCET.

SIR,—In reply to Dr. Hett's letter, which appeared in your issue of the 21st inst., will you permit me to point out that the elongated prepuce to which he refers is usually (if not always) a result of the neglected phimosis. If therefore the manœuvre I suggested be performed as soon as the child is found to have trouble in micturition, Dr. Hett's plea for circumcision will rarely, if ever, be valid. I feel by no means sure that, provided the phimosis be remedied, a long prepuce will cause any inconvenience at all; and I think we should be sure we are on very safe ground before we counsel any attempts to improve upon nature by mutilation. But Dr. Hett makes the strange remark that retraction of the elongated prepuce for purposes of cleanliness will be prejudicial to the *morale* of the child. Upon this principle it were well to inculcate the universal practice of circumcision. For, I take it that every male child should have its prepuce retracted from time to time, whether there be phimosis or not, and the parts carefully washed. To assert, then, that a proper act of sanitary cleanliness can possibly prejudice the mental or bodily well-being of the little boy is to me very startling doctrine indeed. I am, Sir, your obedient servant,

Norfolk-terrace, W., Aug. 25th, 1886. HERBERT SNOW.

PSORIASIS SOLARE.

To the Editor of THE LANCET.

SIR,—Could any of your readers suggest a remedy for psoriasis solare? There is no specific history, but the patient's grandmother suffered from the malady. It appears all over the body. The usual remedies have been tried—arsenic, iodide of potassium, chrysophanic acid ointment, &c. Has anyone found good results from Barff's boro-glyceride? If so, I should be glad to know the method of application, &c. Any other suggestion would be greatly esteemed.—I am, Sir, yours obediently,

Aug. 21st, 1886. HOUSE SURGEON.

THE PREPARATION OF SKELETONS.

AN account has recently been published of a novel industry, to which a large manufactory in the suburbs of Paris is devoted—viz., the preparation of skeletons for the market. The proprietor contracts for a supply of corpses from all the dissecting-rooms and hospitals in the city, and the raw material on its delivery is boiled for days in a cauldron. The grease which rises to the surface is skimmed off and sold; the bones are carefully cleaned and bleached in the sun, and finally assorted and converted into articulated skeletons. The preparation of frogs, lizards, and various reptiles occupies a separate department. The comparative cheapness and abundance of the skeleton supply from Vienna since the Russo-Turkish War has somewhat depressed the trade; but really good osteological preparations, as might be expected, always command a good price. For what purpose the grease which is sold is used is not stated, though we hope the silence is not to be regarded as significant.

R. N.—1. The examination of Englishmen for the degree of Brussels through an interpreter in the English language.—2. The degree is not at present registrable in England, but may become so under the new Medical Act.—3. At St. Andrews, if holding British qualifications and above the age of forty.

Mr. J. Young.—The omission was corrected in our last issue, p. 390.

EXTRAORDINARY CASE OF NEGLECT.

To the Editor of THE LANCET.

SIR,—As showing to what a condition humanity may sink when surrounded by filth, drunkenness, and moral degradation, and because it has never previously fallen to my lot to witness such a case, I send the following.

At midnight on Friday last I received a note from the coroner of the district, requesting me to make a post-mortem examination on the following morning of the body of a girl aged nine years, the daughter of a tramp, who had died in a field at Swalecliffe about 2.30 that afternoon. The body lay in a barn, and upon entering a horrible sight presented itself. Innumerable maggots were crawling in all directions from the back of the head, and upon moving the body the entire mass of matted hair fell off, leaving the scalp as though it had been shaven. At the back of the neck was a large opening, through which could be distinctly seen the skull, stripped of its pericranium, and the entire space filled with a teeming mass of maggots; none were visible on any other part of the body. The day before her death the child had fallen down in a fit, for which brandy was administered, when she revived, and afterwards walked a distance of two miles. The next day she had two more fits, in the second of which she died. As the child had received no medical attendance, all that could be gleaned of her history was that she had measles four years ago, since which she had sores on her head; so that it seems probable that these sores, being neglected, formed a nidus for the fly, the larvæ of which exactly resembled those found on fly-blown meat. I am, Sir yours truly,

Whitstable, Aug. 25th, 1886. JNO. W. HAYWARD, M.R.C.S.

THE METROPOLITAN POOR-LAW MEDICAL OFFICERS.

THE Metropolitan Poor-law Medical Officers, instead of benefiting to the extent of only £18 a year, as stated by error in our last issue, have gained from the Metropolitan Poor Act, 1867, £18,000 per annum, this sum being wholly independent of what has been saved by the fact that they do not now find medicines or persons to dispense them—i.e., they get their salaries without deduction of any kind.

Mr. Edward C. Kingsford might with advantage apply to Moore and Co., 125, Houndsditch.

Mr. William Tebb.—We must decline.

TREATMENT OF STOMATITIS.

To the Editor of THE LANCET.

SIR,—Would any of your readers be good enough to advise me as to the treatment of a lady, aged thirty-five, who suffers from very frequent attacks of stomatitis, occurring in patches on the mucous membrane of the mouth, tongue, and œsophagus. The parts are red, raw-looking, and feel hot and sore. She has no appetite, and little sense of taste. Each attack comes on rapidly, and continues about a week; then she is almost well for a few days. Nitrate of silver, sulphate of copper, lime, tar capsules, &c., with regulation of diet and attention to general health, have been tried in vain. She becomes worse. For years she has been subject to severe sick headaches. I am, Sir, yours truly,

Aug. 19th, 1886. M.B.

SUBCUTANEOUS INJECTIONS OF MERCURY IN SYPHILIS.

To the Editor of THE LANCET.

SIR,—There is a slight error in Mr. Bloxam's paper on "The Treatment of Syphilis by Subcutaneous Injections of Mercury." Twenty minims of the solution he uses contain one-fourth of a grain of perchloride, not one-third. I am, Sir, yours faithfully,

Mary Abbott's-terrace, W., Aug. 21st, 1886. JAMES LATTEY.

moderate.

ERRATUM.—In the Manchester letter last week, p. 377, fifth line from the bottom of first column, for "medical" read *educational*.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Sir Joseph Fayrer, London; Dr. Cullingworth, Manchester; Dr. Herbert Snow, London; Mr. Bellamy, London; Dr. Pearse, Haslemere; Mr. Wetzel; Mr. W. Curran, London; Miss Mason, London; Messrs. Pratt and Co., London; Dr. Cherton, Leeds; Mr. Hopkins, Bath; Dr. Elliott, Aylesbury; Mr. St. Dalmas, Leicester; Mr. Saunders, Bromsgrove; Dr. Gay, Leamington; Mr. Moulding, Clotham; Mr. Furneaux, Shanklin; Mr. Cookson, Hendon; Dr. Reid, Staffs.; Messrs. Medical Diary for the ensuing Week.

Monday, August 30.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M., and each day at the same hour.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.

ST. MARK'S HOSPITAL.—Operations, 2 P.M.; Tuesdays, same hour.

CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M.; Thursday, 2 P.M.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.

METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.

ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITALS.—Operations, 2 P.M., and each day in the week at the same hour.

Tuesday, August 31.

GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Mondays at 1.30 and Thursdays at 2 P.M.

ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.

CANCER HOSPITAL, BROMPTON.—Operations, 2.30 P.M.; Saturday, 2.30 P.M.

WESTMINSTER HOSPITAL.—Operations, 2 P.M.

WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

Wednesday, September 1.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.

MIDDLESEX HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour. Ophthalmic Operations, Tuesdays and Thursdays, 1.30 P.M.

ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Skin Department, Tuesdays and Fridays, 9.30 A.M.

ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour.

LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.

GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Saturday, 2 P.M. Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.

ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.

KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.; and on Friday, 2 P.M.; and Saturday, 1 P.M.

Thursday, September 2.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Surgical Consultations, 1.30 P.M.

CHARING-CROSS HOSPITAL.—Operations, 2 P.M.

NORTH-WEST LONDON HOSPITAL.—Operations, 2.30 P.M

Friday, September 3.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1.30 P.M.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

Saturday, September 4.

MIDDLESEX HOSPITAL.—Operations, 2 P.M.

SUBSCRIPTION.

POST FREE TO ANY PART OF THE UNITED KINGDOM.

One Year	£1 12 6	Six Months	£0 16 8

NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post-offices letters addressed to initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on page 2, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

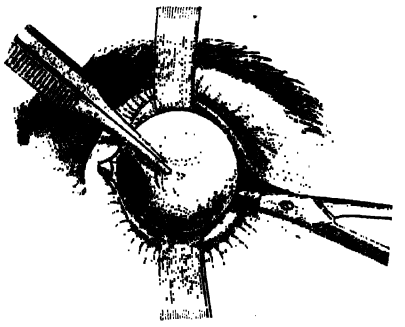
Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed.

Advertisements are now received at all Messrs. W. H. Smith and Son's Railway Bookstalls throughout the United Kingdom and all other Advertising Agents.

Agent for the Advertising Department in France—J. ASTIER, 66, Rue Caumartin, Paris.

Clinical Lectures ON DISEASES OF THE EYE.



Delivered at the Nottingham and Midland Eye Infirmary.

BY CHARLES BELL TAYLOR, M.D., F.R.C.S.,
SURGEON TO THE INFIRMARY.

LECTURE IV.

GENTLEMEN,—A short time ago I had in my service a somewhat eccentric old gentleman—since dead, I regret to say,—on whom I had operated for cataract in both eyes. In return for my kindness he said he would never leave me, and I managed to find employment for him in various ways. One of his errands was to fetch pigs' eyes from the butcher's shop. "What does your master do with those eyes?" said one day a curious customer, who had noticed his frequent visits. "Oh, he fills up the sockets of the eyes taken out at the infirmary with them." "And can the patients see?" "Certainly," he replied. "I have had both eyes done myself." My informant assured me that the man believed him. Perhaps he did—who knows? *Populus vult decipi.* Thousands, I am told, believe a newspaper canard to the effect that a certain German professor has recently succeeded in grafting a rabbit's eye into a woman's head, and that his previously blind patient has since recovered most excellent sight. You and I know, of course, that such transplanted orbs, even if retained in whole or in part, must of necessity be sightless; but we cannot expect the general public to be equally well informed; and it is, moreover, a fact that we are able to accomplish far more in the way of transplanting both homogeneous and heterogeneous tissue than would *à priori* seem possible. For instance, I have succeeded myself in forming an excellent stump for an artificial eye by grafting a piece of prepared sponge into the orbit. And you have seen me again and again so far sever the existing connexions of the eyeball as to be able to turn it round, lift it out of the socket, and then replace it. (Fig. 1.)

FIG. 1.

Here is a patient on whom I performed this operation two years ago. She was sent to me in order that the right eye might be excised. I thought it a pity, however, to sacrifice such a good-looking organ, and therefore divided the optic and ciliary nerves. Now, as you see, she is as well as ever; motion of the eyeball in all directions is absolutely perfect, and, in point of fact, you cannot without careful examination tell which eye has been done. (Fig. 2.)

Here is another patient, a labouring man, operated upon six weeks ago, who has long suffered from recurrent attacks of pain and inflammation in the right eye. As these attacks resisted all treatment, including neurotomy of the supra-orbital nerve, adopted by his surgeon, it was decided to send him to me for excision. Again I thought it a pity to sacrifice a good-looking though sightless globe, and therefore divided the optic and ciliary nerves. As soon as the operation was over he exclaimed, "Thank God, my pain has gone." Now he is as well as ever; motion is perfect; you cannot tell which eye has been done; and he is trebly grateful—grateful for relief from pain, grateful for his preserved eye, and, last though not least, grateful because he has been spared the annual expense and daily annoyance of an artificial substitute, which latter to a working man is something greater than you can readily conceive. It has been suggested by a shrewd and excellent friend of mine that this case is a very pretty one so far as it goes, but that it is by no means certain that we have done with it. "It is," he says, "on the cards that the pain may return." True, no doubt it may return; it might return even if the eye were excised. I was once about to perform this very operation upon a gentleman similarly afflicted, when another surgeon intervened and excised the globe. In that case the pain did return, and of course it might return in this; I do not think it probable, however; and if it does, we are by no means at the end of our resources.

There are three principal objections to this operation. I will name them in the order of least importance. First, it has been asserted that the eye projects in a ghastly fashion after enervation of the globe; second, that it wastes away; and third, that the nerve becomes so perfectly reunited to the eyeball that the patient is in exactly the same condition very shortly after the operation that he was in before it was attempted. This line of argument reminds me of that adopted by the gentleman who was accused of laming a horse which he had hired. He said, first, that the animal was lame when he took him out; second, that he was sound when he brought him in; and third, that he never had him at all. Gentlemen, it is not true that the eye protrudes in an unsightly fashion after optico-ciliary neurotomy, and experience has amply demonstrated that it is not materially altered either in volume or consistence; while, with regard to reunion of the nerve, we all know that if a nerve is divided and the cut ends maintained in apposition, it will reunite: there is nothing wonderful in that. Our veterinary friends have long been aware of this fact, and, in operating for navicular disease, are always careful to excise a portion. But apposition of cut ends is not a state of things that obtains after division of the optic nerve; the eye is an exceedingly mobile organ, and it is difficult under any circumstances to imagine such accurate reunion as would suffice to establish lymphatic circulation, such as modern pathology has taught us is necessary for sympathetic infection. Here is an eyeball the subject of neurotomy six years ago, which I excised, for reasons to be hereafter explained, last week. In this case, as you see, there is not the slightest re-formation of nerve tissue; in fact, the moment the nerve is divided the eye turns outwards and the cut ends are at right angles to each other—a position which may moderate.

FIG. 2.

be readily maintained until all chance of re-attachment of the shrunk extremity to the globe is gone. Here is a patient in whom, as you see, I have taken this precaution. (Fig. 3.) Moreover, I am entirely of Professor Schweigger's opinion that the risk of reunion may be absolutely prevented by excising a portion of the nerve. Let me illustrate my meaning. The elephant is an animal that takes six feet at a stride, walks six miles an hour, and in the open can overtake the swiftest runner; yet it is well known that a trench of only seven feet in width will stop his progress absolutely—he cannot get over it to save his life; and I am convinced that if you will only cut a gap in the optic nerve of ten millimetres in extent or thereabouts, you will just as effectually stop the progress of that *bête noire* of the ophthalmic surgeon—sympathetic infection.

Now, gentlemen, I am quite prepared to be told that if this operation, so far as cutting off the connexion with the sound eye is concerned, is equivalent to enucleation, and if it possesses so many advantages as regards the life, comfort, and personal appearance of the patient, it is very strange that I should be constantly excising eyes at this institution, sometimes as many as three and four in a day. Well, it does seem strange; and there is no doubt that, in our overweening anxiety for the patient's welfare, we do excise many eyes that might be safely retained.

FIG. 3.

But the eyes that we take out at this institution are for the most part eyes that have been crushed by a blow that has probably at the same time felled the patient; eyes that are the site of neoplastic growths which may prove malignant; eyes that have been penetrated by foreign bodies, and which retain their dangerous guests, or which belong to patients who cannot be trusted either to take care of themselves or to return if threatened with sympathetic ophthalmia. In all such cases it is no doubt the best because the safest practice to excise the globe at once. The case is different, however, when the eye, although sightless, is to all appearances perfect; when it is merely affected by neuralgia, slight recurrent inflammations, or luminous spectra, which torment the patient; when it is desirable to render a stump insensible, to preserve a *moignon oculaire;* or when the patient is threatened with sympathetic ophthalmia and obstinately refuses to submit to enucleation of the globe. In all these cases, especially the last, neurotomia optico-ciliaris is a precious resource, and will, I feel convinced, be so regarded by all good surgeons whose motto is *primum non nocere*, and who are, as I am sure we all are, specially anxious that their patients shall be, if no better, at least no worse off for anything that has been done.

There are three principal methods of performing this operation—Landesberg's, Schoeler's, [illegible] Landesberg enters the orbit from the inside, Schoeler from the outside, and Meyer clears a large way by dividing both straight muscles. I prefer to operate from the inside myself, simply because the optic nerve enters the eyeball to the inside of its posterior pole, and is therefore more readily reached in this direction. I pinch up the conjunctiva immediately over the insertion of the internal rectus muscle, cut the tendon as in Graefe's operation for squint, pull the eye forwards, turn it inwards, and divide the nerve as far back in the orbit as possible; the eye is then rotated, and the piece of nerve left attached to the globe shaved off as close to the surface as possible; the cut ends of the muscle are then united by a suture, and the operation completed by the application of a compress bandage. Hæmorrhage, which sometimes proves a source of trouble, may be arrested by using the now insensible eyeball as a tampon, and pushing it well back into the orbit. I have never seen suppuration follow this operation, and only one case of slight ulceration of the cornea, which rapidly healed. One great advantage of the procedure is that you can always operate in time. Sympathetic ophthalmia never occurs until after the lapse of a month or thereabouts from the date of the injury to the exciting eye; and if the patient absolutely refuses to submit to enucleation, you have always this operation in reserve. Speaking on this point, Professor Meyer of Paris remarks that sympathetic ophthalmia "Une fois déclarée poursuit généralement son cours même après l'enucléation du premier œil. Cette opération [resection] doit donc être considérée comme un moyen préventif dont l'application constant est inévitable aussi long temps que l'on ne peut déterminer avec certitude les cas de ce genre que resteraient toujours à l'abri de l'ophthalmie sympathétique." "You had better let me remove the eye," I sometimes say to patients who come to this institution. "Are you going to take it out?" "Yes." "Shall you put it in again?" "No." "I'll come again on Thursday." Such patients never do come again; and I have a painful recollection of two fine fellows, now absolutely blind, who lost their sight through this insane dread of having their eyes "took out." If, however, you call them back and promise to restore the eyeball, as in the operation for neurectomy, they will not hesitate a moment. It is not the permanent loss of the sight—already gone—of one eye which they dread so much; it is the sacrifice of the globe itself which they regard with such very natural horror. Another advantage is that in young persons you are enabled to preserve a tenant for the socket, and so prevent comparative atrophy of the orbit and that side of the face which forms so distressing a feature in some of these cases. Again, it enables us to render a stump insensible and fit to receive an artificial eye. For instance, I recently operated on a lady for cataract in the left eye who had lost her right through a similar operation performed elsewhere. I was fortunate enough to succeed in restoring her sight, and when she could see she naturally wished to improve her appearance by wearing an artificial substitute. I said, "You must let me remove the remains of the lost eye." "Never," she exclaimed, so I divided the optic and ciliary nerves. Now she is able to wear an artificial eye, motion is as perfect as in the modern operation of exenteration, and she looks much better than she would have done had she submitted to my original proposition.

Gentlemen, I have heard it whispered that the operation of enervation of the eyeball has proved fatal. I can find no record of any such accident myself, and suspect that the number of these operations are as yet too few to have contributed their quota to the tables of mortality. If it should do so, however, in due course we ought not to be surprised, for the risks of this operation are precisely those of enucleation *bien entendu*, neither more nor less, and I have known two deaths from the latter operation myself, and quite a number have been recently recorded by other surgeons. It has also been alleged that this operation has been followed by sympathetic ophthalmia in the other eye. I can only find a record (Leber's) of one such case, but when neurectomies are sufficiently numerous I have no doubt that the number will be multiplied. Mooren, Knies, Smidt Rimpler, Pagenstecher, Steinheim, Horner, Critchett, White, Nettleship, Bowers, Ayres, Snell, Lawson, Carter, and others, all record cases of sympathetic ophthalmia following enucleation, and whatever follows enucleation may of course follow resection; the only difference between the two operations is that sympathetic ophthalmia is probably less likely to follow resection than enucleation, simply because in resection it is absolutely necessary to cut the nerve as far back in

the orbit as possible, and you are thus more likely to remove the whole of the inflamed or infected portion of the nerve than in the ordinary operation of enucleation. No doubt we are occasionally obliged to enucleate after neurectomy; the eye you see on the table was enucleated by myself—I now believe unnecessarily—six years after neurectomy from an excessive dread of sympathetic ophthalmia. It has also been alleged that recent researches, especially Poncet's experiments on animals, have tended to discredit this operation, but the contrary is the fact. The only experiments on animals with which I am acquainted are those performed daily by our veterinary friends, and they show conclusively that if a sufficient piece of nerve is removed it never reforms; moreover, it was formerly supposed that the channel of communication between the two eyes in sympathetic ophthalmia was through the medium of the ciliary nerves; that opinion is now exploded, Deutschmann's researches having conclusively shown that it is the optic nerve, its lymphatics, and lymph spaces, which are alone the source of danger, the only bridge by which sympathetic ophthalmia, or ophthalmia migratoria as it ought to be called, can travel from one eye to the other. Speaking on this subject, Professor Schweigger of Berlin remarks, "It is not necessary to remove the exciting eyeball if by exsection of a piece of the optic nerve we can remove the bridge by which the inflammatory process travels from the injured to the non-injured eye"; he adds, that "neurectomy, while as efficient a prophylactic measure as enucleation, has the great advantage that it neither sacrifices the eyeball nor renders an artificial eye necessary." Professor H. Knapp of New York, in a recent paper on exenteration, says, "the mutilation from enucleation is a source of life-long misery and misfortune to many a sufferer in all classes of society." I have myself heard one of our most eminent ophthalmologists remark that "anything is better than a glass eye"; and I know one noble lord who absolutely refuses to wear one. It is for the opponents of neurectomy to explain away these facts and answer these arguments, to prove that we may not in certain cases obtain all the benefits of enucleation by a less severe operation, and one which is not only a *moyen préventif*, but is also unattended by any mutilation whatever; meanwhile, whatever may be the result of further discussion of this important question and extended experience of the operation of neurectomy, I am sure you cannot go wrong in adopting it in such cases as those I have pointed out.

We shall now proceed to operate upon our patients. There are five cases needing attention: one of these is a small boy with neoplastic growth following injury of the eye, which will require extirpation; another is the subject of traumatic cataract, which I propose to extract *secundum artem*—i.e., according to recent enlightenment, without iridectomy; a third is suffering from infecting ulcer of the cornea, which I shall treat after Nieden's plan with the electric cautery; and two others, both adult males, who have singularly enough come in to-day, who will afford me an opportunity of showing you the operation of resection which I have just described.

Remarks after operation.—Gentlemen, I need not now detain you with any remarks upon the first three cases you have just seen. With regard to the last two, the elder is sixty years of age. He comes from a large town in Yorkshire, and for three years past has been suffering more or less, and at varying intervals, from the effects of an accident to his right eye, which was cut across the centre by a chip from a boiler which he was mending. I saw him for the first time to-day, and he informed me that he has been in an eye infirmary, and that the surgeon, whose skill is well known, wished to take his eye out, an operation which he declined then, and again when I suggested it to him to-day. He came here, he says, "because he thought I might relieve him without taking his eye out, and if I could not do so he should return as he came." I suggested neurectomy, to which he submitted without a moment's hesitation, and which, as you saw, was performed without misadventure. Now the eye is quite insensible, and I have no doubt that we shall have succeeded in relieving him from pain, annoyance, and attacks of recurrent inflammation, which have again and again prevented him from using the sound eye. The younger patient was injured by the bursting of a gun; his forehead was wounded by a chip of metal, and the right eye has been peppered with powder; he has bare perception of light with this eye; I cannot illuminate the fundus oculi, and the pain he has suffered since the accident three weeks ago has deprived him of sleep, and, according to his own account, rendered life unbearable. I could not ascertain that the eye had been penetrated by any solid substance, and it was clearly desirable that we should relieve his pain with as little injury as possible. I therefore, as you saw, divided the optic and ciliary nerves. As soon as the effect of the ether had subsided he declared that his pain had quite gone, and I think we have reason to believe that this happy state of things may continue. Should we, however, be disappointed, we always have enucleation in reserve. I may mention that some forms of neuralgia may be relieved by division of the ciliary nerves only, an operation which was first proposed by Von Graefe, and first successfully carried out by Professor Meyer. The operation was then performed by incising the eyeball, but it may be just as well accomplished by division of the nerves behind the globe, by separating the tendon of the internal and external rectus muscle and feeling *à tatons*, as it were, down to the optic nerve. I have here a little girl from the blind asylum who has been entirely relieved of neuralgia in this way, and two others—adult males—in whom the operation has been equally successful.

I thank you, gentlemen, for your attendance and assistance this evening. The next lecture will, I hope, prove specially interesting to you, as I intend to discourse upon eye diseases as they occur in general practice.

AN OBSCURE CASE OF FEMORAL HERNIA;

OPERATION; NECROPSY.

By EDWARD BELLAMY, F.R.C.S.,

FELLOW OF KING'S COLLEGE AND SURGEON TO CHARING-CROSS HOSPITAL.

THE patient, S. H——, a female aged sixty-seven, came under my care on Nov. 5th, 1885, with what was diagnosed as a large left femoral hernia, evidently containing omentum. She had been ruptured, as far as I could ascertain, since 1867, and the hernia had never entirely returned within the abdomen since its first appearance. She had never worn a truss. Owing to bronchitis she had been coughing a great deal of late, and on the morning of the day I first saw her, after a more than usually severe fit, the rupture increased very much in size and gave her intense pain. Although she had been sick after the coughing fits for two months, she had had no *pain*, which would seem to fix (?) the period of strangulation to the morning of the 5th. The bowels were normally opened on Nov. 3rd, when there was a period of rest for several hours, and the symptoms were very slight, the tongue somewhat furred, pulse 100, and her vomiting *biliary*. At 8 P.M., under ether, an attempt was made at taxis, but resulted in failure. At 9.30 it was again tried and again failed, so I at once proceeded to operate, under strict antiseptic precautions. By a straight incision about four inches long I exposed a loop of intestine seven inches long, nearly black but still glistening, and a mass of omentum as large as my fist, but showing no signs of strangulation, and to which evidently the coil of intestine was attached. After dividing what I supposed were the constrictions, I found I could not reduce the bowel, and believing that my being unable to do so was possibly the adherence of the mass of omentum, after clamping it beyond, I excised it with scissors and tied each bleeding point separately. With a little manipulation I then succeeded in returning—as I thought, and as did those present—the liberated gut into the abdominal cavity.

Nov. 6th.—The patient was sick, but free from pain, and passed a motion. Pulse 120; tongue moist. The wound was dressed under spray, and looked very well.—7th: Again very sick, and some pain in abdomen, but no local tenderness. Pulse 116.—8th: The same. Pulse 130.—9th: The same. The temperature suddenly fell to 96°, and she died somewhat suddenly at midday. I may state that I had made up my mind to perform a second operation, but her condition clearly showed that no good could possibly come of it.

Before making any remarks, it will be advisable to read the post-mortem notes, as made twenty-four hours after death by my friend, Mr. Stanley Boyd:—Body well nourished, rigor mortis moderate. Post-mortem congestion marked.

There is a wound about four inches long, a little below Poupart's ligament at its centre. There is a little greenish discolouration about its upper part. Slight union has occurred between the edges, but is easily broken down. The finger passes into a cavity which surrounds the femoral opening. On opening up the wound, a small piece of intestine, about the size of a pigeon's egg, is found to have descended through the canal and to have become strangulated. It is for the most part a deep purple colour, but its anterior part is yellowish, and may perhaps indicate commencing slough. Its surface is still polished. The saphenous vein runs upwards just internal to this opening. It is full of yellow red thick fluid. This had been clearly brought down again by coughing. The deep crural arch and the external pillar are notched to the depth of one-third of an inch immediately above the ring. Abdomen: The lower part is swollen and occupied by a considerably distended coil of small intestine, exhibiting the signs of early peritonitis. The large intestine and stomach are empty and uninflamed. The liver is driven up. There is very little fluid in the peritoneal cavity. Below, this distended bowel leads to the femoral ring, which it enters. Issuing from the wound is a perfectly collapsed piece of bowel, which occupies the deep part of the abdomen. Tracing the dilated portion upwards, it is found to cross the abdomen from right to left beneath the mesentery of that piece of bowel which is impacted in the femoral opening. This band is moderately tight, and does not seem to have produced any extra strangulation. On the left of it the bowel ends in the duodenum. Dependent parts of bowel are much congested, but no sign of nipping is found in any part of the intestine within the abdomen. On removing the dilated bowel, the omentum and small intestine (the former bringing down with it the transverse colon) are found matted together by adhesions, some of which are recent, but others, especially those binding the omentum to the abdominal wall, seem to be old. The piece of bowel immediately below the opening is of a blackish colour, and adherent by very soft lymph to a thick mass of omentum which is firmly adherent to the left side of the inner opening of the femoral canal. The femoral canal is now laid open from above. On the omentum, after removal from the canal, are found the two ligatures applied during life, so loose that the handle of a scalpel passes beneath them easily. Round about the omentum is a quantity of the same thick red fluid which was found in the saphenous vein. As to the bowel, that portion which lay external to the ring is found to be continuous with a considerably larger portion lying in the cavity between the peritoneum, on the one hand, and the horizontal ramus of the pubic bone with the obturator internus on the other. This cavity contains a little red fluid of offensive smell. The intestine in this cavity is everywhere of a deep purple colour, in many places becoming opaque. The sides of the coil are pretty firmly adherent to each other, and it seems to contain some rather solid masses. The strangulated portion joins the intestine in the abdomen by a strongly constricted neck, which remains well marked even after removal from the body and the removal of all constricting bands. A little force, however, sends gas from the strangulated into the intra-abdominal portion. The intestine contains the usual plum-coloured offensive fluid, with a little fæces. The thick masses are simply greatly swollen portions of bowel wall. Towards the omentum, everywhere the wall looks as if hæmorrhages had taken place into it. At the point of constriction the entering intestine is thin and fibroid, not ulcerated. The piece leaving the hernia shows no sign of nipping upon the mucous membrane. The bowel above is full of fluid fæces. That strangulated, and below the point of strangulation, contains a good deal of mucus in addition to the prune-juice-coloured fluid. It is now found that there is another cavity between the peritoneum and the body of the os pubis, shut off from that above described by a complete membranous septum having somewhat the feel of omentum. Below, it is continuous with the inner wall of the femoral sheath. What the contents of this may have been there is nothing to show. The strangulated piece is about 7 ft. up from the ileo-cæcal valve, and its length is about 6 in.

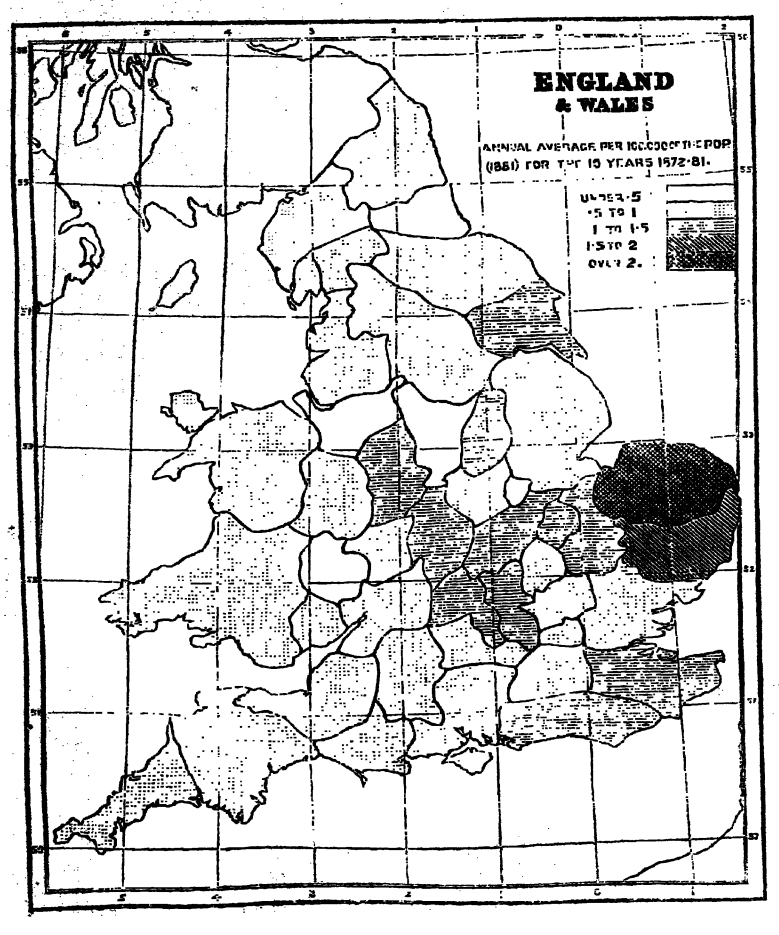
Remarks.—It seems to me that the case is one of extreme rarity, and that the following are the chief points of interest: the very short duration of the symptoms which called for operation, considering the age of the patient and the time she had suffered from rupture; the unsuspected condition found on the post-mortem examination, of which there was not the slightest evidence during the kelotomy; the persistence of symptoms after operation, or rather their recurrence, suggesting a second operation, which was about to be performed. From the condition of the parts, it is quite evident that the coils of intestine must, at each reduction on the patient's or medical attendant's part, have been invariably returned into one or other of the cavities above described. The secondary operation I should have performed would have been a laparotomy. The question is, How far, from what one knew of the case, there is evidence to have justified it being the primary one.

Wimpole-street, W.

ON CALCULOUS DISEASE.

BY CHARLES B. PLOWRIGHT, M.R.C.S., F.L.S.,
SENIOR SURGEON TO THE WEST NORFOLK AND LYNN HOSPITAL.

Distribution of Calculus in England, Scotland, and Ireland; Distribution of Allied Diseases—Gout, Rheumatism, and Diabetes; Annual Death-rate; Influence of Rainfall, of Season, of Cyder-drinking, &c.



THIS proverbial frequency of calculus in Norfolk has called forth many explanations, none of which can be regarded as satisfactory. It has been attributed to the prevalence of east winds; to the consumption of the Norfolk dumpling, of beer, and of water impregnated with chalk; to the deficiency of milk, and to other causes. The town of King's Lynn is situated on the Great Ouse, and this river sharply limits the distribution of our stone cases. Of the last fifty cases treated at the Lynn Hospital, forty-eight came from the east side of the river and two only from the west. As this circumstance sweeps away the east wind, the dumpling, the beer, and the deficiency of milk theories, only the chalk theory is left. Professor Latham has written a good deal recently upon the formation of uric acid in the body, but neither he nor anyone else has yet explained how chalk in the human laboratory can be converted into uric acid. It happens, unfortunately for the chalk theorists, that those parts of the county of Norfolk in which calculus is most common are not the chalk districts; and, conversely, that the chalk districts, although not absolutely stone-free, produce a much smaller proportion of cases than do the gravelly and sandy districts. Next to Norfolk, as a stone-producing county in the United Kingdom, comes Aberdeenshire, a district from which chalk is absent. In Aberdeenshire the prevalent theory is the consumption of brose. But brose is unknown in Norfolk, and, moreover, is an article of diet not confined to Aberdeenshire; whilst in larger areas in Scotland where brose is consumed the disease is unknown—as, for example, Inverness-shire. With the above facts before us, it is clear that some other explanation exists which has not yet been offered. In the hope of finding the clue to the problem the present investigations were undertaken.

Before advancing any further theories which might or might not stand the test of the geographical distribution of the disease, the present communication will deal firstly with the distribution of the disease in Great Britain. For this purpose we may take the statistics of stone cases of the various county hospitals which have been collected by Dr. Dobson[1] in 1779, Mr. R. Smith[2] in 1821, and Mr. Cadge[3] in 1874. By comparing these we shall find that while no part of England is absolutely free from stone, yet it is much more common in some parts than in others. In the order of frequency are the counties of Norfolk, Suffolk, Huntingdon, Cambridge, Yorkshire, Worcester, Leicester, Nottingham, and Warwick. On the other hand, in the order of rarity are the counties of Hereford, Chester, Devon, Dorset, Derby, Lancashire, Wiltshire, and Cumberland. Unfortunately these statistics are more or less incomplete, no returns being shown from many hospitals. Neither are we able from them to form any trustworthy opinion as to the frequency of the disease to the population. For this purpose we must have recourse to the Registrar-General's reports. Now the great point is, are these reliable?—not from negligence in their compilation; but are the deaths from calculus registered as such really from this and not from allied diseases, such as stricture or enlarged prostate? A good deal of trouble was

DEATHS FROM CALCULUS IN ENGLAND AND WALES.

By CHARLES B. PLOWRIGHT, M.R.C.S.

ANNUAL AVERAGE RAINFALL IN THE REGISTRATION COUNTIES OF ENGLAND AND WALES FOR THE TEN YEARS 1872-81.

By S. H. MILLER, F.R.MET.SOC.

digitalis was of a bright and decided brown, whilst that from 106 grains of Mr. A.'s mixture was only of a light straw colour; and Exps. 4, 8, and 17 in the table of physiological tests show that whilst a nearly equivalent quantity, or 110 grains, produced cessation in systole in twenty and seventeen minutes, 10 minims of tincture of digitalis in the same time only slowed the heart's action from 39 to 18—i.e., the 110 grains of mixture were more powerful than 10 minims of tincture of digitalis, and yet that they did not contain 10 minims is shown by this colour test. The infusion may be excluded also, for a quantity equal in potency to 10 minims of tincture of digitalis, and therefore not so potent as the 110 grains of the mixture, would amount to at least two drachms—that is, the mixture would consist entirely of infusion of digitalis; and this is shown by the specific gravity of 1209, and also by the separation from it by chemical means of fixed oil and cane sugar, not to have been the case. The fourth drug mentioned, convallaria, is not official, and is not much used; still, it is possible, as suggested in an article on these cases in the *British Medical Journal* of March 27th, 1886, that "some of the bulbs of the lily of the valley might have become accidentally mixed with the bulbs of the squill, from which the vinegar had been prepared. The difference in size between the bulbs of convallaria and of squill is very great, but after they were sliced and dried, it is just possible that they might be confounded." Considering, however, that cases of poisoning by squills, although rare, are recorded, we may, I think, conclude that in these instances the syrup of squills was the toxic agent; being of exceptional strength, due to the variation in strength of the bulb, to which I shall refer shortly. It was thought that possibly the stock from which this exceptionally potent syrup of squills was obtained might be existing in the manufacturer's store. Dr. Goldie, the medical officer of health for Leeds, was written to, and requested to institute inquiries of the wholesale dealer who supplied Mr. A. He, however, found no evidence of want of care in preparing the syrup or vinegar; and we have not been able to ascertain the facts relative to the gathering of the samples of squills, either as to date or place of collection; nor to procure a sample from the stock supplied to Mr. A.

Remarks.—The symptoms of poisoning by digitalis, which were not present in the cases which are the subject of this paper, are insensibility and dilatation of the pupils. The recorded cases of death from squill poisoning are so few that before we can give a comprehensive and accurate list of the symptoms we must have a much extended list of cases. I can only find records of two fatal cases in man, and in one of them neither the symptoms nor the post-mortem appearances are given. In the other case, which Christison quotes from Lange, the stomach was found to be "everywhere inflamed." This is somewhat different from the post-mortem appearances in the case of the girl Ethel, where a few inflammatory patches were found; and very different from the appearances in Orfila's two dogs, if we admit them in comparison, where the digestive canal was "normal." The difference may have been due to a possibly fresher condition of the squill bulb that was the cause of death in Lange's case. By drying, the acridity is got rid of (Pereira). Hagar mentions a volatile oil which would be dissipated in drying, and Landerer found in the fresh bulb a bitter extractive, which he did not find in the dried one. The heart, in the case of the dog recorded by Fagge and Stevenson, was found full of blood; the heart had stopped in diastole. Concerning this I would quote Brunton, who says, in reference to the whole group of cardiac poisons, "This stoppage of the heart in systole occurs in frogs, but in higher animals the heart may stop in diastole." Hager mentions four active principles as present in the squill; of these, two arrest the heart's action in systole, and one in diastole. It may be that the two former are more readily absorbed by the frog's tissues than the third, and that the contrary is the case with the dog. The experiments which I have made and recorded here simply show (and are not intended to show more) that with the chemical extracts made from the mixture delivered to me I obtained the same results with the frog's heart as with a known poison belonging to the digitalis group, and pharmacologists and toxicologists agree in saying that the members of this group all produce the same effect on the frog's heart. Death of the heart ensued in Experiments 4 and 8 in seventeen and twenty minutes; whilst the time recorded by Fagge and Stevenson in poisoning by squills is fourteen to twenty minutes. That the symptoms in those children and the post-mortem appearances in the case o the one that died are consonant with what little we know of squill-poisoning I shall endeavour to show. These children had been taking half a teaspoonful of syrup of known squills twice a day for ten weeks. Squills is cumulative in its action; therefore small doses might occasion death after some weeks' administration. But we cannot suppose that this cumulative effect should occur at so nearly the same time in children of the age of three and a half and five, when both were taking the same dose. Add to this fact that a single dose of the mixture last made up caused intermission of the pulse in a child of eight (Lilian). Squill varies in strength; the outer scales are stronger than the inner (the outer scales contain more scillain); the fresh bulb is stronger than the dried (volatile oil and Landerer's extractive is lost in drying); the bulb gathered in summer is stronger than that gathered in autumn (in summer the squill contains less sugar, and the increase of sugar in the autumn is probably due to the sugar which is one of the two bodies into which glucosides split up): the red variety is stronger than the white. That the squill varies in strength is shown by Experiments 13, 14 and 15, in which the same quantity of syrup of squills from three different sources produced the following effects: In Experiment 13, in forty minutes it slowed the pulse from 38 to 36; in Experiment 14, in forty-seven minutes from 36 to 10; and in Experiment 15, in thirty-eight minutes from 36 to cessation. From some variation in the strength of the squill used — probably from imperfect drying — a syrup was presumably made, containing in poisonous proportion the active principles which are normally present, but in smaller quantities; and this exceptionally strong syrup was used in dispensing the last mixture which the children took. This view of the matter is confirmed by the fact that Mr. A.'s syrup, taken from the same bottle which he had used in making up this last mixture, had an intense and persistent bitter taste, like that mentioned as possessed by scillitoxin, the glucoside which arrests the heart's action in systole.

The following symptoms observed in these children are mentioned by authorities quoted:—Paralysis of the legs—Orfila (dog), Pereira (rabbit), Fagge and Stevenson (dog). Nausea and vomiting—Orfila (dog), Christison (man), Pereira (man), Fagge and Stevenson (dog). Drowsiness—Orfila (dog), Christison (man). Sudden accession of death—Orfila (dog), Fagge and Stevenson (dog). Hurried respiration—Orfila (dog), Pereira (lower animals). Intermittent pulse—not mentioned.

Post-mortem appearances.—Lungs normal—Orfila (dog). Intestines normal—Orfila (dog). Fluid blood—Orfila gives one case as containing only fluid blood, another had blood clots.

Conclusions.—1. That squill is not a safe drug to use for routine, and especially popular or lay, practice. 2. That being so variable and, when strong, so potent a drug, it should be looked upon by the profession as unsuitable for use until a solution of standard strength can be produced. 3. That in the meanwhile its use should be discontinued.

Nottingham.

REMARKS ON THE GENERAL TREATMENT AND DRESSING OF WOUNDS.

By JAMES WHITSON, M.D., F.F.P.S.G., F.R.M.S.,
ASSISTANT-SURGEON TO THE GLASGOW ROYAL INFIRMARY.

DURING the last few years the treatment and dressing of wounds have undergone a marked change for the better. The introduction of the antiseptic system has led to improvements in both these ways which not long ago were undreamt of. Prior to this great epoch in surgery, wounds of any magnitude were daily to be seen discharging large quantities of pus, and at brief intervals epidemics of pyæmia decimated the wards of hospitals in a manner truly alarming. Under an antiseptic *régime*, however, these complications have been banished as if by the enchanter's wand, and at the present time suppuration is a factor with which we seldom require to deal, while pyæmia and hospital gangrene are scourges almost unknown. To all who were familiar with the difficulties surrounding the early elucidation of the subject, it need scarcely be remarked that the realisation of such a degree of excellence has not been achieved at a single bound. On the contrary, the standpoint now held by anti-

septic surgery has only been attained after years of toil and as a result of much wearisome labour, for scientific research of permanent value is invariably a plant of tardy growth, and even under propitious circumstances can only reach maturity by degrees. Like all other departures from an old routine, the antiseptic system had many prejudices to overcome, and in its initial stages may be said to have been evolved slowly out of a perfect chaos of disorder. Those who were Sir Joseph Lister's pupils during the time he held office in the Glasgow Royal Infirmary will recollect that his first attempts to prevent putrefaction in wounds were exceedingly rude, but gradually under the light of increasing experience the methods pursued by this eminent surgeon became more perfect, though the principle as at first laid down by Lemaire remains unshaken to the present hour: "The wound which suppurates, as I hope to demonstrate presently, is a secreting surface, the products of which become altered under the influence of air, and give birth to a series of phenomena due to one and the same cause—fermentation."

If decomposition arises in a wound, the processes of repair become disturbed, nutrition is interfered with, and a condition of septicæmia of more or less pronounced type is necessarily established. Fortunately for patient as well as for surgeon, complications identical with those just described can be obviated by a rigorous adherence to antiseptic laws. In addition to the destruction and subsequent exclusion of the various forms of organism constantly present in the atmosphere, and which find in the living tissues a congenial habitat, there are a number of other points attention to which is essential for the successful progress of wounds generally. Prominent among these are arrest of bleeding and drainage. Blood when effused into a wound cavity should be permitted a ready exit, because when retained it clots in a comparatively short time, and with the transformation from the fluid to the solid condition all chance of future escape short of opening up the flaps is frustrated. If small the clot may be absorbed and thus prove of no consequence, but if present in excess a mass of this kind assumes the characters of a foreign body, and unless removed will speedily give rise to irritation. Hence the danger arising from the confinement of much effused blood, and consequently there stands out all the more prominently the need for the prevention of such a complication by the thorough arrest of hæmorrhage in wounds prior to the suturing of their edges. A little time spent in securing the different blood vessels will amply repay the original outlay.

In carrying out excisions, it is a good plan to pack the fresh wound firmly with green protective and rolls of gauze dusted with iodoform[1]. The layer of protective should be inserted first[2]. By placing it next the tissues no débris of gauze is permitted access to the wound, and owing to its smooth, non-adherent surface, there is at the same time the additional advantage that when we remove the stuffing—which is best done forty-eight hours after the operation—the whole of it comes away easily in a body. By the end of this time all hæmorrhage has usually ceased, the steady compression exercised on the divided blood vessels during the interval being in the great majority of instances sufficient to occlude their mouths, and the edges can then be approximated without trouble.

A dependent system of drainage is what we ought to aim at. Blood, so long as it remains fluid, obeys the ordinary law of gravity by seeking its lowest level; consequently, the lower the aperture for its passage outwards, the greater the area operated upon and the more complete the evacuation. Drainage may be carried out either with the aid of the indiarubber tubes of Chassaignac or by means of the decalcified chicken-bone tubes of Macewen. For recent wounds the latter are to be preferred to those of indiarubber, and if threaded with hair the principle of capillarity is called into play and a syphon action induced.[3] Hair has, however, the disadvantage of not draining pus, and where suppuration exists indiarubber tubes should be used.

The suturing of wounds demands care and attention. Dragging of the stitches is a complication which must be carefully guarded against, and if tension on the margins of the flaps supervenes, inflammation of the surrounding parts will certainly follow unless the strain be promptly relieved. In order to avoid this and secure immediate union of the edges, we frequently make use of button-sutures, and in excisions generally they are valuable auxiliaries in the conduct of the case.

The proper dressing of a wound is indispensable for its satisfactory progress. Unless in those instances where the discharge has become septic, dressings should be removed as seldom as possible, absolute rest being a *sine qua non* for the progress of healthy repair. In the carrying out of this important item our great aim should be the selection of a dressing in which are united a capacity for ready absorption and a subsequent power of maintaining the parts in a state of asepticity. Fortunately we have at our disposal materials answering these requirements more or less completely. Of the various dressings which are placed in contact with the skin, there are none, *cæteris paribus*, superior to gauze. Being porous, it permits of the ready penetration of blood or serum through its meshes, and when properly prepared and in fresh condition its antiseptic powers are undoubted. Eucalyptus gauze is preferable to the carbolised variety, though at present it possesses the drawback of being the more expensive of the two. Owing to the volatile nature of antiseptic principles, both kinds of gauze should be placed in air-tight boxes as soon as saturation is effected. By this means evaporation of their essential constituents is prevented. For a number of years after the introduction of the antiseptic system layers of gauze surrounded by an outer layer of jaconet composed the dressing placed over a wound; but in following what was then the ordinary custom, experience soon showed, if there was much oozing, as there frequently is after major operations, that stains quickly made their appearance at the lower end of the dressing, thus necessitating its frequent removal, and thereby forcing us to adopt a most objectionable practice. In order to obviate this alternative, recourse can be had to layers of carbolised tow, which when thoroughly teased form an excellent supplementary dressing. The compression exercised by rolls of this material is regular and steady, and owing to the elastic nature of these when enveloping a limb the circulation is unlikely to be interfered with, even though the bandages are put on somewhat tightly. Any discharge which happens to pass outside the gauze is taken up by the tow, and in consequence of the impregnation of its fibres with carbolic acid a state of asepticity is maintained for a much longer time than could be done without it, and repeated changes of dressing are thus rendered unnecessary. Of late, however, tow, and to a considerable extent gauze, have come to be superseded by wood-wool as well as by wood-wool wadding, two forms of external dressing not without special merits. Both possess considerable absorbent power,[4] and when made into pads of the requisite size and thickness do admirably to envelop the first two or three layers of gauze. In the preparation of the wood-wool pads care should be taken to see that the wool is properly distributed throughout, so that the pressure which is afterwards brought to bear on the underlying structures may be equable.[5] It will be found, for example, that wood-wool is superior to tow in checking any tendency to oozing immediately after an amputation by the regular compression which it exercises over and for some distance around the stump, while the immobility which its presence confers is a factor in furthering the after-progress of repair, which should not be lost sight of. When a dressing is intended to remain on for some time, it is advisable to adopt the precaution of dusting the gauze and wood-wool we purpose employing with iodoform. The powder in question is a reliable germicide, and corroboration of this property has been frequently witnessed in several of the wards of the Glasgow Royal Infirmary, where a species of fungus used regularly to develop itself in the gauze which was at one time supplied, but it was always noticed that the organisms never appeared or encroached upon the area sprinkled with iodoform—a test which clearly proved the value of the compound in checking the spread of such a

[1] In excisions of the elbow-joint this is best done prior to the removal of the elastic bandage.

[2] The protective plaster will answer the purpose best if perforated. When this precaution is taken, any effused blood speedily finds its way through the perforations into the gauze, and is thus removed *in toto* along with the stuffing.

[3] The hair is best removed at the end of forty-eight hours, as all serous or sanguineous discharge has usually ceased by that time; but when the dressing is intended to remain on for some weeks, this adjunct should be dispensed with.

[4] Wood-wool and wood-wool wadding take up blood or serum readily, but neither absorbs pus well, and where suppuration is going on the dressings require to be frequently changed.

[5] After the wood-wool is placed within the bag of gauze which holds it together, threads may be passed through the pads at regular intervals and secured on either side by means of buttons. If this arrangement is followed, shifting and consequently lumping of the wool are prevented

form of life. The elastic bandage is a valuable agent in the treatment of wounds of any size. When properly applied, it maintains the dressing firmly in its place, and by so doing ensures the keeping up of steady compression—points which contribute in no slight degree to promote the general weal.

The ideal wound may be defined as one which heals with a single dressing. In Dr. Macewen's wards during the past year not a few amputations of limbs, as well as excisions of mamma, have only received a primary dressing, and when looked at for the first time at the end of three weeks were found to be healed.[6] In all these, decalcified drainage-tubes without hair were used, and on the removal of the first dressing the whole extent of the tubes were found to have been consumed by the tissues, with the exception of the small portions or ends protruding from the lips of the wounds, and which on inspection were seen to be lying loose on the layer of gauze placed next the skin. It is obvious, therefore, that in aseptic cases, where we can maintain the dressing without change for several weeks, decalcified drainage-tubes are superior to those of indiarubber, from the fact that they leave no sinus behind, and after their first insertion require no further notice to be taken of them.

It is almost unnecessary to add that perfection in surgery, as in other pursuits, cannot be attained without the expenditure of much time and labour. In all the cases referred to the greatest pains were taken to secure the whole of the divided bloodvessels.[7] The stitches were carefully and regularly inserted, so that there was no dragging on the edges of the flaps. A thorough system of drainage was established, and by means of suitable dressings the parts were maintained in a state of asepticity and at absolute rest. Finally, the temperatures (taken twice daily in the rectum) were examined at every visit, with the view of detecting and rectifying the slightest departure from the normal order of things.

Glasgow.

ON CLERGYMAN'S SORE-THROAT.

BY THOMAS WHIPHAM, M.B., F.R.C.P.,

PHYSICIAN TO ST. GEORGE'S HOSPITAL, AND IN CHARGE OF THE DEPARTMENT FOR DISEASES OF THE THROAT.

PATHOLOGICALLY, the condition known as clergyman's sore-throat is but little understood; etiologically, perhaps, there is quite as much obscurity surrounding it. All writers on the subject are agreed that it affects persons who are in the habit of over-exerting their voice, and in Dr. Mackenzie's experience there is "in almost every instance evidence of constitutional delicacy, and most of the patients present an anæmic appearance."[1] Those who are especially liable to the affection are the clergy, singers, hawkers—persons, in short, who make undue use of their voice under more or less adverse surroundings. There is nothing surprising in the fact that the hawker or the costermonger is particularly prone to the disease, seeing that he is, in the pursuit of his calling, exposed to all the vicissitudes of the weather in England. Schoolboys shouting even in genial weather for any length of time become hoarse from laryngeal congestion; the costermonger, less well cared for, shouting for a much longer time, day after day maintains this congestion of his larynx, pharynx, and fauces as a chronic condition, which when once established is constantly aggravated by ever-recurring atmospheric changes. It seems, however, scarcely fair to compare the case of the clergyman, who suffers so much from this complaint, with that of persons who are compelled to vociferate in the open air. Moreover, the clergyman, unless he be of the Boanerges type, does not make such violent use of his vocal apparatus as does the hawker or the costermonger. Yet the clergyman, in spite of the fact that the exercise of his voice is limited by the walls of his church, in spite of his more comfortable surroundings, is especially liable to this inflammation of his pharynx, larynx, and fauces. A better comparison would be instituted between the clergy and the bar—another profession in which great and prolonged vocal efforts are frequently required, and whose members are not, as a rule, sufferers as the clergy are. It may be interesting to compare the circumstances under which the members of each of these professions exercise their respective vocations.

The first point which naturally suggests itself is the prevailing atmospheric conditions in the two cases; and if it be conceded that a cold, damp, badly ventilated church might be an efficient cause of the malady in the one case, it cannot be contended that the stuffy and impure air of a court of justice would be likely to confer immunity in the other. Probably the reverse would obtain, for it is by no means uncommon for a person spending the evening in an unventilated theatre to become quite hoarse towards the conclusion of the play. Such causes, then, may be dismissed as being the prime cause of the disease in question. Doubtless they predispose to and aggravate the inflammation, but its origin and maintenance can scarcely be attributed to them alone. The internal arrangements of the church and the court of justice next arrest attention. Among the Greeks and Romans, whose amphitheatres were open to the sky, it was of paramount necessity that every assistance should be afforded to the orator or to the actor in the matter of acoustics. Consequently, the audience were placed above, or at least on a level with, the person who addressed them. Thus he could speak, *ore rotundo*, with his head erect. So, nowadays, in forensic practice, the judge and jury are seated on a plane considerably above the counsel, who speaks from the floor of the court. Theatres and lecture-rooms are in the main, for the same reason, arranged on this plan. In a church the position of the audience and the speaker is exactly reversed, and whether reading or preaching the officiating clergyman is always above the heads of the majority of his congregation. A few years since, before many of the modern restorations of churches had been effected, the position of the two was even worse; for then the clerk was on a level with the congregation, below the reading-desk, and the desk was below the pulpit, so that the preacher occupied, during the period when the most strain was thrown on his voice, a position which almost necessitated a forward and downward inclination of his head.

How far, then, is such an arrangement effective as a cause or aggravation of the condition known as clergyman's sore-throat? In order to ascertain what happens when the clergyman or the barrister is addressing his audience, it is only necessary that anyone should read aloud from a book any passage in a clear and distinct tone, holding his head erect, as the barrister does, with his chin perhaps slightly elevated. In this position the tone of his voice is clear and penetrating; moreover, phonation under such circumstances is performed with a minimum of exertion to the reader. Now let him continue his reading, and, so far as possible, neither increasing nor diminishing his efforts at distinct articulation; in other words, let him make no attempt to raise his voice, but at the same time let him, as he reads, allow his head to fall gradually forwards, as the clergyman does, so that his chin shall nearly rest on his sternum. The change in the voice will at once strike the ear of the listener, who will straightway appreciate the muffled and indistinct tones which accompany the forward inclination of the reader's head; while the impossibility of maintaining clearness in articulation, without a compensatory raising of his voice, is equally manifest to the reader. He becomes sensible of a want of tension of his fauces, uvula, and soft palate, and experiences a sensation of partial closure of the normal faucial orifice. If, with his head prone on his chest, he would attain the same power of voice as before, when his head was erect, he must increase his muscular efforts, and even so muffling of each word is to a great extent unavoidable. If, however, muffled words were the only outcome of reading or speaking with the head thus thrown forwards and downwards, the result might not be an important one. But the serious effect of it is that the friction of the air passing through the relaxed faucial aperture is very greatly increased, and this increase of friction tells especially on the fauces and the pharynx, against which the soft palate and pillars of the fauces are pressed. Thus, hyperæmia is established in the parts which are affected by this excessive friction; and temporary hyperæmia, if frequently encouraged, speedily becomes chronic congestion. Now, the clergyman, placed as he is above the heads of his congregation, is almost compelled, unless he be an extempore preacher, to perform the greater portion of the service with his head inclined forwards and downwards. Doubtless, many of the clergy know the prayers &c. by heart, but even so most of them from force

[6] The last sixteen amputations of limbs and the last five excisions of the breast have healed with a single dressing.

[7] In the amputations of limbs the greater number of the arteries were tied before the removal of the elastic bandage, so that this class of operations may be described as practically bloodless.

[1] Diseases of the Throat and Nose, vol. i., p. 31.

of habit usually assume a position of the head as if reading from their book. In the case of leading men at the Bar, elocutionary efforts are often both severe and prolonged, and immunity from throat affection cannot in their case be claimed on the ground of the lightness of their labours in this direction. The attitude of the barrister, with his head erect when speaking in court, is widely different from that of the officiating clergyman. It is not difficult, therefore, to see in this fact alone a possible explanation of his immunity from this particular affection of the throat. Further, it is equally probable that failure to maintain the head erect in the performance of the services of the Church, furnishes the explanation of that chronic inflammation of the pharynx, fauces, and palate to which the clergy are so especially liable.

It is desirable that communications to a medical journal should be limited in length, and these remarks will be concluded by only a brief allusion to the cases of two clergymen, the most recent which have come under observation. One officiated in the East-end of London, the other in the midland counties; both suffered from the throat affection under consideration. The duties of the latter were performed under peculiarly trying circumstances, in that the country round was low-lying, damp, and often flooded; his church was a large one and "very difficult to preach in," and in the winter months was extremely cold and damp. In consequence of this he frequently caught severe colds. His throat, when he first came under notice, had been at various times a source of trouble and annoyance for eleven years; he was a good preacher, and was given to deliver long sermons. In the other case the symptoms were of shorter duration, and had commenced two years and a half previously—a time at which he had renounced alcohol for example's sake, and had entered on his ministrations at the East-end. The tonsils were especially affected in this instance, but the pharynx and pillars of the fauces were involved in the inflammatory process. Local applications—e.g., glycerin. boracis at first, and subsequently astringents, were prescribed, with rest and change of air in the latter case. Both patients, who confessed to a habit of "hanging the head" when in the reading-desk or pulpit, were duly cautioned against the practice; both subsequently expressed in strong terms their sense of "a speedy relief to their sufferings," owing to the ease and comfort with which their services were performed with the head in the natural position for phonation, and both were satisfactorily relieved for the time. Instances might be multiplied from among those engaged in reading to the sick or in teaching, but the two mentioned may, it is thought, be considered typical and of sufficient interest to direct the attention of the clerical profession to what may prove to be a simple though important factor in the treatment of a most distressing malady.

Grosvenor-street, W.

ON THE CAUSES AND PREVENTION OF FLAT-FOOT.

By M. P. MAYO COLLIER, M.S.Lond., F.R.C.S.Eng.,
SENIOR ASSISTANT-SURGEON TO THE NORTH-WEST LONDON HOSPITAL.

SOME novel departures in the treatment of flat-foot have been lately brought before the profession. The fascination of novelty, and not necessity, is the mother of these inventions. The present treatment of flat-foot is founded on erroneous notions of its anatomy and causes.

It is incorrect to describe the antero-posterior arrangement of the bones of the foot as a bridge, and the astragalus as the keystone. A bridge usually has two extremities, fixed immovably, so resisting the tendency of forces from above to flatten the arch, the keystone being the highest point and centre of the convexity. Now, the arch of the foot has only one fixed point—the inner tuberosity of the os calcis; the other extremity of the arch is constantly changing its position, and moves considerably forwards when supporting the weight of the body. The astragalus cannot be likened to the keystone of a bridge, as it does not transmit equally to both extremities of the arch the weight of the body. The greater part of the weight of the body is transmitted directly through the os calcis to its inner tuberosity; only a small part, comparatively, is transmitted through the head of the astragalus and scaphoid to the anterior extremity of the arch. A glance at a vertical section of a normal foot will immediately convince one that such must be the case. The concavity on the under surface of the astragalus fits the saddle-shaped articular surface on the upper aspect of the os calcis accurately, permitting no gliding movement forwards, but only a rotation of the astragalus inwards on the sustentaculum tali as an axis. A movement forwards of the astragalus on the os calcis in the normal position of the foot is impossible, as the sustentaculum tali fits into the concavity between the two articular facets on the under aspect of the astragalus. A movement forwards is impossible when the sole of the foot is resting on a horizontal surface. As proof (if need be) of this assertion, in the normal position of the os calcis the astragalus, being unconnected by ligaments or other structures, will support any appropriately arranged weight, without slipping forwards or becoming displaced.

In the light of these facts, it is perfectly evident that the chief cause of "flat-foot" cannot be due, as stated by most authors, to "a general want of tone in the fibrous structures of the body." The plantar fascia and ligaments maintain the normal position of the os calcis, and these in their efforts are assisted by the tendons passing under the lesser process of the os calcis. Ligaments are only capable of bearing a certain strain, and when continually stretched will atrophy and yield. They yield because they are over-strained first; they perform their function satisfactorily as long as they have their normal duty to perform. They do not grow weak or atonic first, and then stretch, but after being unduly strained they then grow weak and stretch. I wish to point out and maintain that the flattening of the foot is not due primarily to weakness and laxity of the ligaments, but to an antecedent alteration in the position of the os calcis. I have stated that the os calcis is capable, in its normal position, of supporting the astragalus and any reasonable superimposed weight, without the intervention or necessity of ligaments or other bonds of union. This statement holds good as long as the foot rests on a horizontal surface. If the foot rests on a surface, so that the heel is raised above the level of the toes, the weight of the body is not transmitted so directly to the posterior half of the os calcis. The saddle-shaped surface on the upper aspect of the os calcis becomes an inclined plane, sloping downwards and forwards, and, consequently, favours a sliding movement forwards of the astralagus, thus throwing the weight of the body on the calcaneo-scaphoid, interosseous, and plantar ligaments. An intermittent and occasional strain these ligaments can well stand, but a constant and continuous strain ends in atrophy, weakness, and stretching. In pointing out how constantly this cause of flat-foot is at work, we have only to reflect that each and all of us walk and stand under these abnormal conditions; the heel always being raised above the level of the sole of the foot, and with some misguided individuals to the extent of several inches. In most cases the strain is intermittent, but where constant and continuous, as in omnibus and tram-car conductors, operatives in factories, shop assistants, and others, where constant standing is necessitated, how common is this affection! Dr. Little says, "a slight degree of atonic valgus is common in girls, especially in those of the upper and middle classes; less common in boys." Why not in the less fortunate and often badly nourished females of the lower classes? Because the high heel is less prevalent in the lower than in the upper classes, and less common with men than women. For the prevention of flat-foot I would say, Don't wear a heel: let the sole of your boot be perfectly flat.

One word about treatment. It is a constant practice with surgeons in cases of flat-foot, when not too far gone—when the patient is capable of walking, although with discomfort,—to order a pad of leather or other material to be placed on the inner side of the boot to support the arch. Does this support the arch? And how can it? In flat-foot the arch is destroyed. It may compress the internal plantar nerve between the pad and the head of the astragalus, and so become intolerable; but if it does not do so, it is a source of considerable comfort to the patient. Why a pad in the boot on its inner side is a source of comfort to the patient is that it belts up the anterior extremity of the os calcis, and maintains it in its nearly normal position, counteracting the effect to some extent of the displacement, directing the weight of the body to the inner tuberosity of the os calcis, and removing the strain from the plantar structures. The treatment of these cases is simple when

not too far advanced; good food, fresh air, and as much rest as possible, with a radical change in the construction of the boot. The toe and heel should change places, or, what amounts to the same thing, a good laced boot should be worn, with the sole quite an inch thick in front, fining off to a line or two at the heel. By these means the normal inclination of the os calcis would be maintained, and the weight of the body properly disposed of.

New Cavendish-street, W.

FATAL CASE OF CHOREA ASSOCIATED WITH RHEUMATISM AND CARDIAC DISEASE.

BY MARTIN OXLEY, M.D.,
CONSULTING PHYSICIAN TO THE LIVERPOOL INFIRMARY FOR CHILDREN.

THE following interesting case has recently come under my notice:—

Harriet B——, aged ten years, had measles, scarlet fever, and whooping-cough before she was three years old. At the age of five she was in the Infirmary for Children suffering from rheumatism and chorea. She was admitted into the infirmary on the 21st of April of this year. Her mother stated that three weeks previously she began to suffer from rheumatic pains in her joints, and that one week before she was brought to the infirmary chorea set in. On admission the patient complained of pain in the right knee and right wrist. She was also suffering from a well-marked attack of chorea, most marked on the right side. The choreic movements were more violent during the night, when awake, than in the daytime. The heart's apex beat in the fourth and fifth interspaces, internal to the nipple line. There was slight epigastric pulsation. A rough systolic thrill could be felt over the apex. There was a loud grating systolic murmur heard most distinctly over the axilla. There was no œdema or albuminuria. A few days after admission she had clonic twitching of the right side of the face, accompanied by incoördinated movements (described by the house-surgeon as being like an infant's convulsion). The patient improved considerably, and on May 25th she was sent to our convalescent home at Waterloo. She remained there for three weeks, and seemed to be improving in health and benefiting by the sea air. On her return (June 14th) to the infirmary, it was noticed that there was much greater impulse over the cardiac region, and that the apex was now outside the nipple line. The chorea had disappeared, and she was allowed to be up and about the ward. A few days after her return she was noticed to have a slight rise of temperature at night (101°), and she was ordered back to bed. On July 2nd the heart symptoms became much more marked, and her face and feet became œdematous. From this time she became rapidly worse, and died on the morning of July 11th.

Post-mortem examination.—There was slight œdema of the legs and eyelids. Heart very much enlarged, displacing the lungs, especially the left, and extending, partially covered by the thin edge of the lung, about half an inch to the right of the sternum and to the lower border of the second left rib. Pericardium: A patch of thick, firm, white adhesion, about the size of a sixpence, situated over the right ventricle near its apex, attached the two layers of pericardium; there were no other signs of pericarditis. On the surface of the aortic, mitral, and tricuspid valves, minute vegetations about the size of a pin's head were to be seen grouped in clusters. The aortic and mitral valves were both incompetent. The lungs were congested and œdematous all over; the left pleura was slightly adherent at the back. The liver was most typical nutmeg, and a large and apparently recent infarct was found on section.

Remarks.—This case, taken with others which have been reported, help to strengthen the opinion held by many, that rheumatism and heart disease are responsible for chorea; and the fact that in chorea we frequently cannot find evidence of heart disease is no proof that there is no valvular disease. This was very well illustrated in a case which I brought before the members of the British Medical Association at their meeting in Liverpool in 1883. It just happened that many of my colleagues were examining cases in order to supply information to the Collective Investigation Committee, and a patient who was under my care at that time was frequently examined with the view of detecting heart disease. No cardiac bruit could be detected, and there was no apparent hypertrophy; yet, notwithstanding, after death, which occurred unexpectedly during the chorea from exhaustion, vegetations about the size of pin's heads were found to fringe the aortic and mitral valves. In both these instances the vegetations were very small, and were very readily detached from the valves. In two other fatal cases of chorea which I have had under my care, the patients being of the ages of seven and eleven respectively, one had vegetations on the aortic and mitral valves, while the other had well-marked pericarditis and nodular rheumatism as described by Drs. Barlow and Warner.

Liverpool.

NOTES ON TWO CASES OF STRYCHNINE POISONING.

BY FRANCIS E. MARSTON, L.R.C.P. LOND., M.R.C.S.

THE following cases of strychnine poisoning, one homicidal and the other suicidal, having come under my observation during the last seven months, may not be without some interest to the readers of THE LANCET.

I was called to see W. M—— at 6.35 in the evening of June 14th, 1886. The patient was lying on his shop floor, complaining of great pain over the epigastrium, a feeling of suffocation, and of being very thirsty; he was very restless, and his face wore a somewhat anxious expression. On being questioned, he replied that he had drunk some porter from a jug which had been given him. The jug was handed to me, and found to contain about a drachm of porter, with some small white crystals at the bottom and some clinging to the sides of the vessel; they had a very bitter taste. Thirty grains of sulphate of zinc were administered, and a stomach-pump was sent for. After the lapse of ten minutes from my arrival the patient was seized with convulsions of a tetanic character, which left no doubt as to the poison taken. Mr. Herbert Hawksworth, who had arrived on the scene, assisted in introducing the stomach-pump, and the stomach was thoroughly washed out with water, the washings being nearly colourless. The patient had two more violent convulsive spasms, with only a slight intermission. There was great lividity of the face; and the lips were retracted, showing the teeth firmly closed. He was quite conscious during the intervals of the fits, and requested to be turned over on his side. During the second spasms, which were of increased severity, the patient died (6.55 P.M.). The emetic acted only slightly. Probably about fifty-five minutes elapsed from the poison being taken until the time of death.

Mr. Hawksworth and myself made a necropsy twenty-one hours after death, when the following notes were recorded:—The whole of the body was extremely rigid, the upper extremities being slightly flexed and the hand clenched; feet markedly arched; no opisthotonos; the mouth tightly closed, and the face wearing a somewhat agonised expression. The membranes of the brain, and the substance of the brain itself, were congested; the medulla and upper part of the spinal cord were slightly congested, but otherwise appeared healthy. The stomach showed a few patches of congestion, and contained about five ounces of thick grumous straw-coloured fluid, consisting of partially digested particles of food, and smelling of alcohol. The duodenum and upper part of the small intestines were healthy, and contained fluid similar in appearance to that in the stomach. Lungs intensely congested, and engorged with blood. Heart of natural size; its muscular substance soft and flabby; cavities nearly empty, the little blood they contained being fluid and very dark. Here and in every other part of the body the blood was not coagulated. The rest of the organs appeared healthy. Bladder empty and strongly contracted. The trowsers contained an evacuation of fæces.

The stomach and its contents were sent to Mr. T. Blunt of Shrewsbury, the county analyst. One-tenth of a grain of commercial strychnine was found in the contents, and the washings obtained by the stomach-pump contained a little more than one-tenth of a grain. In the jug from which W. M—— drank the porter six grains of strychnine were found. Fifteen grains of strychnine is the quantity supposed to have been thrown into the jug.

One fact about the case seems at first sight rather curious: why the washings obtained by the stomach-pump returned nearly colourless, when at the post-mortem five ounces of thick grumous material were collected from the stomach itself. This may have occurred, I think, in two ways: either that during the first spasm the stomach contracted and forced the contents into the duodenum, leaving the stomach empty, which regurgitated during the last spasm at the time of death; or that the stomach had an hour-glass contraction, the pyloric end containing the liquid, leaving the cardiac end empty. Though no signs were visible at the post-mortem, the former view seems the most likely; the duodenum, as mentioned before, contained fluid exactly similar to that in the stomach.

The other case of strychnine poisoning occurred in December last, when a man took the whole of a sixpenny packet of vermin-killer in a jug of stout with a suicidal intent. In this case the spasms occurred in about twenty minutes from the time of drinking the porter; and when I saw the man some ten minutes later, the tetanic convulsions were well developed, occurring every few minutes, but sometimes as much as seven or eight minutes occurred between the spasms; the least touch seemed to produce them. The patient was quite conscious between the fits, and when asked how he felt, made the somewhat graphic remark, "I feel as if I was floating round hell." Emetics were given without effect. Chloral and chloroform were resorted to; the convulsions decreased in severity, and at the end of eight hours had disappeared, and the patient recovered. He was a strong healthy man, over six feet in height. Each sixpenny packet of the vermin-killer contains on an average a grain and a half of strychnine.

Welshpool.

INFANT FEEDING.

BY E. PAGET THURSTAN, M.D. CANTAB.

THIS is a question of great interest to every medical man, and one on which the last word has not yet been said, I think. On the ground that the salivary and pancreatic secretions are hardly present in a new-born child, it is always stated in books that food of a farinaceous nature should be avoided entirely in arranging the dietary of very young children who require to be brought up by hand. In theory this is true; in practice it is not. Owing to the mechanical difference in the nature of the curds of human and cow's milk, there is probably always some difficulty for children in digesting cow's milk, while in some cases it is very great. This difficulty is generally recognised, and the usual explanation given is that the milk is too rapidly curdled, and sets into a single hard mass, to which the digestive agents can get no access. Fermentation proceeds too far, and the result is either vomiting of large masses of curds, or constipation, the motions also consisting mainly of undigested curd with marblings of green and yellow. I quite agree with this theory, but I do not agree with the usual mode of treatment advised.

It is generally recommended, if the milk curdles (1) to add lime-water; (2) to add barley-water; (3) to add dilute concoctions of linseed; (4) to employ solution of isinglass; (5) to use cream and water, excluding the curd; (6) to abandon milk altogether, and use veal-tea, beef-tea, or well-skimmed mutton-broth. This last plan is of great service, when in hot weather acid fermentation is quickly developed, or when alarming vomiting and gastritis occur; but it is obviously only a temporary expedient. As regards the other plans, the favourite and almost routine treatment is the lime-water plan. Now, lime-water, so far as my experience goes, sometimes *produces* sickness; and, any way, it cannot be right to give *medicine* daily for months if there be any reasonable alternative, for what we want in these cases is a diet which can be given for months together without producing indigestion. Of the other plans enumerated above, the cream-and-water diet, seems to be excluded by the fact that the curd alone possesses the nitrogenous casein which is necessary for perfect nutrition. The problem we have to solve is how to make the curd digestible; to exclude it altogether is to cut the Gordian knot.

The preparations of barley, linseed, or isinglass are not open to the above objections, but there are practical difficulties in the way of preparing them suitably in sufficiently small quantities at a time. The theory on which the use of these is founded is that in children with excessive secretion of gastric acid the milk can be prevented from curdling too rapidly by adding something to thicken the milk and entangle the curds as they form. This theory is plausible, and, to my mind, explains the facts fairly well. On this view the function of the barley-water or isinglass is mainly, if not entirely, mechanical. If so, why not allow a small amount of farinaceous food on the same ground? I have accepted the logical deduction from this reasoning in my practice, and I feel sure that no diet produces so uniformly good a result as milk thickened with farinaceous food of some kind. The crust of bread (when free from alum and large quantities of potato starch), Brighton biscuit, or one or other of the well-known infants' foods may be used, but only in very small quantities, so that the milk can still be sucked through the tube of a feeding-bottle. I do not think it much matters which "food" is used, as I believe that when given in this way in early life its function is mainly mechanical—viz., that the particles of solid entangle the curds as they form, and prevent them coalescing into one large mass. It must be borne in mind that many people hold the view that this tendency of cow's milk to form masses is not due to any excessive acidity in the child's stomach, but to a provision of nature, whereby the calf is able to regurgitate the milk and ruminate. I do not know whether it is a fact that calves chew the curd as their mothers do the cud, but it is certainly the case that the condition of acidity in the child has something to do with it, for it is a known fact that the offspring of gouty and rheumatic parents have more trouble in the way of digestion than the, in other respects, more delicate infants of scrofulous or tuberculous parents.

It has been proposed to overcome the difficulty of digestion by preparing milk with pepsine and pancreatine. Now this plan seems to me objectionable. Nature's revenge on all parasites is to deprive them of the organs which they refuse to exercise. If we habitually rear children without putting them to the necessity of digesting their food for themselves, we ought not to be surprised if we finally evolve a race of beings totally without digestive functions of any kind! Short of this extreme view, the tendency does not seem a wise one.

Finally, we ought perhaps to consider the claims of condensed milk. That the curd of this milk is more digestible than the curd of most forms in which milk is taken is, to my mind, indisputable. A new drawback, however, makes its appearance. Condensed milk is, in plain English, milk jam, and the excess of cane sugar produces indigestion in a new way, while, moreover, the condensation seems to deprive the milk of much of its saline constituents, and removes material required for bone formation.

We are forced back, then, to the farinaceous foods in very small quantities, added to cow's milk and water, as being the best artificial diet for children. The vendors of the various foods for infants lay great stress on the fact that the starch of the wheat has undergone some chemical change which renders it easier of digestion. This may be true to some extent; the diastase, when present, may convert a portion of the starch, but this (in the early weeks of life, at all events) is probably a secondary function. The following case which has recently occurred in my practice will illustrate my views, and, I think, confirm their correctness:—

The wife of a well-to-do tradesman was prematurely confined of a female child nine weeks before she was expecting; the presentation was breech and footling. When the child was born, it was cyanosed and made no attempt to breathe. After performing artificial respiration for five minutes the breathing became fairly established; but the child was still cyanosed, and did not cry. I cut the cord and bled the child to two drachms, after which it cried fairly strongly. The mother had never been able to nurse her children, and no attempt to do so was made now. It was fed on milk-and-water, half and half of each. The weather being hot, we had no difficulty in keeping up the warmth of the child, and for a few days all went well, except that the child could not be induced to drink more than half a pint of milk daily. Three days after birth it weighed 3 lb. 8 oz. A week later it weighed 3 lb. 9½ oz. In the meantime the cord and surrounding rag had come away, so that the actual gain could not have been more than an ounce, probably less. Shortly after this, sickness and slight diarrhœa came on. Veal-tea was ordered with the milk, and cream-and-water twice a day, instead of entire milk-and-water. Some

powders were given, containing a third of a grain of mercury and chalk, with a little aromatic confection, ipecacuanha, and rhubarb. The diarrhœa and sickness abated, but the child was still taking very little. Eight to ten drops of brandy were added to the milk three times daily. At the end of another week the weight was 3 lb. 10 oz., being a gain of only ½ oz. The child was now fed on milk, thickened with a little patent farinaceous food. The following week the weight was 4 lb., the gain being 4 oz. The week after the weight was 4 lb. 9½ oz., being a gain of 9½ oz. The child is now doing well.

Here is surely a clear case of a life preserved by a change of diet, and a change, too, from a diet which I may call orthodox to one that is often spoken of as absolutely injurious.

Southborough, Tunbridge Wells.

A Mirror OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

ST. BARTHOLOMEW'S HOSPITAL.

STRICTURE OF THE RECTUM; COMPLETE INTESTINAL OBSTRUCTION FOR TWO MONTHS; PROCTOTOMY; RECOVERY; REMARKS.

(Under the care of Mr. HARRISON CRIPPS.)

THIS case is one of much interest, from the duration of the complete obstruction, and also from the example which it gives of the necessity of examining the rectum in all cases of intestinal obstruction, especially those of a chronic character. There is no statement that the patient had been under medical care previous to his admission into the hospital, nor as to any treatment adopted before that. Whatever it was, no improvement was to have been expected, the presence of this unusually tight stricture not being known. We would refer our readers to the remarks appended to the case on the treatment of this and similar conditions. For the following notes we are indebted to Mr. Elliot, house-surgeon.

J. B——, aged forty-two, was admitted on March 21st. He was quite well till about eight months ago, when he first noticed a fulness after eating, and was constantly troubled with wind. Soon afterwards the bowels became relaxed, the motions being small in quantity and dark in colour. These were passed with much straining, and caused a dragging pain about the anus. Periods of constipation alternated with diarrhœa. For the last two months he has passed no motion at all, but has had a slight discharge from the anus just sufficient to stain his linen. He has slept pretty well, and was able to do his work until a fortnight ago. Since that time he has been in bed. He has vomited once or twice, the vomit being sour, but not offensive. His appetite has been good, but he has purposely avoided solid food for some time. He has lost a considerable amount of flesh.

On admission he was a fairly-nourished man, very sallow and cachectic looking. Tongue furred; pulse 72, of good volume; temperature subnormal. He stated that he felt unwell, but not ill. The abdomen was enormously distended, measuring nearly forty inches round at the umbilicus. No peristaltic movements were visible. The abdomen was universally dull on percussion, and had a doughy feeling, especially in the iliac fossæ, where distinct impressions could be made in the swelling by pressure of the fingers. On examination of the rectum there was found to be a very tight stricture commencing just within the anal margin. The stricture was too tight to admit of even the little finger. With a little manipulation a No. 8 black soft catheter was passed into the stricture, and on withdrawal the eye was found to be blocked with fæcal material, showing that it had passed beyond the contraction. It was again introduced, and a small quantity of warm water passed through it by Higginson's syringe. This flowed back again much stained with fæces. About a couple of gallons of water were thus introduced by instalments of half-pints, coming back each time darkly stained. During the next few days these injections were given twice daily. By this treatment the circumference of the abdomen was reduced about an inch, but no really successful evacuations could be obtained.

On April 1st, under an anæsthetic, a long probe-pointed knife was introduced into the bowel well through the stricture, and the last two and a half inches of the rectum completely divided backwards in the middle line as far as the coccyx, after which several pounds of putty-like fæcal material were scooped out and washed away. During the next fortnight enormous quantities of fæces oozed away, so that by the 16th the girth of the abdomen was reduced to thirty-four inches. Subsequently the case did well. The patient gradually regained power in the muscles of the intestinal wall. A full-sized bougie was daily passed. He left the hospital on June 8th, having perfect control over his motions; and although the passage was free, there was still considerable induration in the last two inches of the rectal wall at the site of the previous stricture.

Remarks by Mr. HARRISON CRIPPS.—The case narrated is of interest in more than one respect. The length of time that complete obstruction lasted without producing urgent symptoms is remarkable. The obstruction had been absolutely complete for more than eight weeks, but during the first six weeks of this period the patient had been able to continue his work; while on admission, beyond the enormous distension of the abdomen, there were no urgent symptoms of distress. The treatment of such a case is a matter of considerable importance, and must depend both on the nature of the stricture and its height from the anus. If the contraction be beyond reach of the finger or so high up that its dilatation or division is impracticable, there can be no question that if enemata fail to give relief colotomy should be performed. If, on the other hand, as not infrequently occurs, the constriction is within easy reach of of the anus, the treatment to be adopted must depend as to whether the stricture is fibrous or malignant. In the majority of instances of malignant stricture the best treatment would doubtless be a lumbar colotomy. It is both an unsafe and an unsatisfactory procedure to divide a malignant stricture, even when close to the anus. The tissues cut through are so rotten that it is difficult to restrain hæmorrhage, while in a few weeks the cut surfaces rapidly develop huge fungoid masses which again block the bowel. On the other hand, in cases of fibrous stricture near the anus, a complete linear proctotomy, dividing the stricture, and including all the parts from the anus to the coccyx, is highly satisfactory. It not only affords immediate relief to the obstruction, but if care be taken to allow the wound to heal over a full-sized bougie, and to have this frequently passed for six months or a year, a cure may be often promised. Fortunately, it is not common for either malignant or fibrous stricture to be allowed to progress so far without treatment as to produce complete obstruction. In cases of cancer of the rectum, in which it has been decided that complete excision is impracticable, so soon as the symptoms of stricture become prominent a colotomy should be advised. To wait until complete obstruction occurs is to condemn the patient to many months of unnecessary suffering, and renders the operation far more hazardous. The operation of colotomy, when performed on an empty bowel in a patient not suffering from exhaustion, is comparatively a safe procedure, but when delayed and undertaken on a distended gut in a patient dying of obstruction the mortality becomes enormously increased.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.

TUBERCULAR ULCER OF THE TONGUE IN A WOMAN; REMOVAL OF THE FRONT PORTION, FOLLOWED BY COMPLETE CESSATION OF THE LOCAL PAIN.

(Under the care of Mr. VINCENT JACKSON.)

RACHEL L——, aged thirty-seven, an in-patient of the hospital, was transferred from Dr. Malet's wards to those of Mr. Jackson on account of a very painful ulcer of the point of the tongue. The woman had been married for several years, but had never been pregnant, and her family history showed that her youngest sister died of pulmonary con-

sumption, a disease from which she was suffering in the upper portion of each lung. She states that six months ago she perceived a hard pimple on the front "edge" of the tongue, which was not preceded by any injury or by any irritation in the front teeth, which are well formed and free from caries. Three months afterwards an ulcer formed and has slowly enlarged, and on account of the great pain which eating and the various movements of the tongue caused, she was anxious, as all local applications had failed to give relief, for something more to be done.

On admission the tip of the tongue was seen to be occupied by a shallow ulcer, oval in shape, measuring half an inch across and a quarter of an inch from above downwards. The floor had a greyish look and was uneven and nodular, the edges being slightly undermined, but there was no surrounding induration, separate nodules, minute ulcers, or enlarged glands.

April 22nd.—The patient being in a semi-recumbent position on a couch, ether was administered, and the mouth being well opened by a gag worked from the left side, the tongue was pulled out and grasped by a pair of long-bladed forceps about an inch from the tip, and about three-quarters of an inch of this portion of the tongue was cut away with scissors. The mucous membrane of the two surfaces was united by ten points of interrupted suture of very fine silk. The tongue being released and no hæmorrhage ensuing, the mouth was closed and the patient removed.

26th.—All the sutures were removed.

May 4th.—Patient discharged. Wound quite healed. The operation has been followed by a complete cessation of all the distressing symptoms complained of previously.

Report of Ulcer of the Tongue, by Dr. HENEAGE GIBBES. The morbid changes consist of a number of tubercles dispersed throughout the substance of the tongue. Each tubercle consists of a number of small, round cells, and one or more multinucleated or giant cells; these vary much in number and size. These tubercles are in various stages; some, especially near the surface, have undergone necrosis in the central parts; and some of those just under the superficial epithelium have destroyed it, and in this way have caused ulcers on the surface. There are a few bacilli to be seen amongst the small cells in the tubercle, but none in the giant cells. This is their usual manner of occurrence in this form of tubercle.

SAMARITAN HOSPITAL FOR WOMEN, NOTTINGHAM.

TWO CASES OF OVARIAN TUMOUR, AND ONE OF HYDRAMNIOS; REMARKS.

Under the care of Dr. ELDER.

CASE 1. *Ovarian Cystoma: Ovariotomy; Recovery.*—Mrs. S——, aged fifty-five, was admitted on May 31st, 1886, suffering from an ovarian cystic tumour of the right side. At the operation the uterine body was found lying in front of the tumour, which had deep intra-ligamentous attachments, and was attached quite up to the right uterine cornu. The cyst was tied off by sections, and drainage was subsequently used. Three weeks after the operation the patient left the hospital well.

Dr. Elder remarked that his object in recording this case was to point out how dangerous, and possibly fatal, tapping under such circumstances would be.

CASE 2. *Ovarian Cystoma of Right Side; Torsion of Pedicle; Ovariotomy; Recovery.*—Mrs. W——, aged fifty-five, was admitted on June 1st with an ovarian cystic tumour. There was a very indefinite history as to the duration of the growth, and although the patient had been confined to bed eight weeks before admission, there was nothing in her state to indicate the condition of the parts as revealed at the operation. There had been no acute seizure indicative of strangulation, no rapid increase of the tumour, or urgent constitutional symptoms. What troubled the patient most prior to admission, and during the few days which elapsed before the operation, was a sense of physical prostration not usually found in the subjects of ovarian disease, coupled with nausea and loss of appetite. Attempts to get about had brought on abdominal pains, from which she was fairly free when lying in bed. There being no seeming urgency, the operation was delayed until June 7th, because of the scanty renal secretion. At the operation the cyst wall was found loosely adherent in front, and so softened that it broke down under the forceps and trocar; in fact, the cyst was semi-gangrenous. In addition to the parietal adhesions, it was also loosely attached to the small intestines, to the omentum, which was much thickened, and to the pelvic peritoneum on the right side. In separating these there was considerable bleeding, and a large section of the omentum had to be removed. The pedicle was found twisted from left to right and on the right side. This was secured by a Staffordshire knot, and after thoroughly washing out the cavity with plain water and sponging, a drainage-tube was left in. The patient made a good recovery, and went out in a little over three weeks. The cyst contents were thick and coffee-coloured; the cyst itself was very friable, in parts easily breaking down under the finger, and its interior was lined by layers of fibrin.

Remarks.—The noteworthy points about this case are (1) the utter absence of those symptoms which are usually associated with twisting of the pedicle; (2) the direction of the twist; and (3) the fact that it was found on the right side, as has by other observers been noted in the majority of instances.

CASE 3. *Hydramnios.*—Mrs. T——, aged forty-two, was admitted on May 5th, from Lincolnshire, as a possible example of ovarian disease. The previous health of the patient had been good, and she had borne ten children. Last November she ceased menstruating, and until six or seven weeks ago neither the doctor nor herself had reason to doubt a natural pregnancy. She then began rapidly to enlarge, and her legs and labia became œdematous. The sudden increase in size prevented her getting about, and in this state she was referred to Dr. Elder. The abdomen was found uniformly distended by an indistinctly fluctuant swelling. The flank percussion note was clear and unaltered by position, but dull in other parts. No fœtal heart-sound could be heard, but the placental souffle was distinct. Per vaginam the cervix was found shortened and broadened, with soft, velvety lips. No information could be obtained by attempted *ballottement*. The breasts were enlarged, secreting milk, and with darkened areolæ. In all other respects the patient's health was good, and careful and repeated examination of the urine showed no trace of albumen. The patient was sent home, with a letter to her doctor, who was advised to induce labour if urgent symptoms superseded. This had to be done shortly after her return, and she was confined of twins. She was dangerously ill, but ultimately recovered.

Remarks.—This is an example of a rare disease depending upon a local pathological condition usually found in women who have borne children, frequently in twin pregnancies, and fraught with great danger to mother and offspring. It has been stated that albumen is always found in the urine of such patients. That this is not so, this example proves.

ST. VINCENT'S HOSPITAL, DUBLIN.

CASE OF ACUTE CHOREA; DEATH.

(Under the care of Dr. QUINLAN.)

For the report of the following case we are indebted to Sydney Johnson, ward clerk.

B. O'L——, aged ten, was admitted on July 26th, suffering from severe chorea, which had been going on for ten days. The day before her admission, her mother, thinking she was "acting," chastised her severely, with the effect of greatly aggravating her symptoms; and, becoming considerably alarmed, she brought her to the hospital.

On admission, the patient was found to be suffering from very severe chorea, principally on the left side, with much tossing of the arms, which had to be gently restrained. The disturbance continued to a great extent through her sleep. She was ordered a dose of castor oil and turpentine.

July 27th.—She had passed a bad night; the symptoms unabated. The castor oil and turpentine to be repeated.

28th.—Chorea rather worse. Great crying whenever touched, and occasionally without being touched. Had slept very badly. Ordered two grains of sulphate of zinc three times a day, to be increased by two grains daily; also at bedtime, ten grains of hydrate of choral, with thirty of bromide of potassium.

29th.—Slept better, but choreic symptoms worse. Crying very much. On searching along the spine a tender spot was found over the root of the brachial plexus; when this was touched immediate opisthotonos was produced. A blister was applied over this spot. The chloral was repeated, and the sulphate of zinc increased in amount.

30th.—Opisthotonos no longer produced, but choreic symptoms very bad. Sleep had been rather disturbed. Temperature 98·6°; pulse 104.

31st.—Choreic symptoms very bad. Sleep much disturbed. Circulation beginning to fail. To continue the sulphate of zinc, ten grains four times a day, and the chloral and bromide draught. Temperature normal; pulse 96.

August 1st.—Rather better; slept well last night, and was quite quiet during sleep.

2nd.—Rather quieter; a good night; taking milk freely. The vibration of the muscles of the forearm, which had previously rendered it very difficult to count the pulse, is much reduced. To continue the treatment.

4th.—Quieter; muscular spasms less; slept well last night. The sulphate of zinc increased to eighteen grains four times a day.

6th.—Considerable epistaxis at 1 A.M.; rather quieter. Sulphate of zinc increased to twenty-four grains four times a day. The sphincters of the bladder and of anus are beyond control, and the evacuations are passed unconsciously.

7th.—First sound of the heart very weak; pulse dicrotic; considerable effusion in the bronchial tubes; chorea less violent. Ordered twenty-six grains of sulphate of zinc with five minims of digitalis four times a day. An ounce and a half of brandy to be given in small quantities during the twenty-four hours, mixed with milk.

8th.—Quiet night; pulse stronger; lungs clearer, but some crying. Ordered thirty grains of sulphate of zinc with ten minims of tincture of digitalis four times a day.

9th.—Fair night; pulse steadier, 108; crying a little. Continue treatment.

10th.—A fair night; face pale; point of nose and extremities cold; not much movement, but great crying; pulse 140 and very dicrotic; first sound of the heart almost inaudible. Continue the sulphate of zinc with ten minims of tincture of digitalis four times a day; omit the chloral draught.

11th.—Had a fair night; chorea has ceased; heart's action very weak; pulse very dicrotic; evidently sinking. Died at 7 P.M. of weakness. A post-mortem examination was not permitted.

Medical Societies.

ACADEMY OF MEDICINE IN IRELAND.

Ununited Fracture of the Humerus, and a Method of Treatment thereof by Metal Screw-Taps.—Electrolysis for the Treatment of Urethral Stricture.

A MEETING of the Surgical Section was held on May 21st.

Mr. HENRY FITZGIBBON exhibited a brace fitted with drills and screw-taps for the fixation of resected bones, and reported a case of Ununited Fracture of the Humerus which he had successfully operated upon by this method. Mrs. T——, admitted into the City of Dublin Hospital on March 13th, 1885, with comminuted fracture of humerus which refused union, was sent to the seaside until Nov. 14th, when she was readmitted with permanent non-union. The patient was operated on successfully on Nov. 26th by means of screw-taps and wire sutures, which were removed on the twenty-first day after the operation. The patient was exhibited to the Academy, with firm union and a useful arm, on April 16th. Mr. Fitzgibbon attributed the non-union to the pressure of the comminuted fragment being displaced inwards so as to cause pressure upon the brachial vessels, depriving the lower fragment of sufficient blood-supply.—Mr. BENNETT corroborated Mr. Fitzgibbon's description of the operation, which, he said, was performed upon a woman who was an unfavourable subject for it both as regards age and nutrition, presenting, as she did, extreme flabbiness of muscle. The union was perfect not only as regarded junction of the bones, but also in their apposition and the line of direction of the humerus, so that there was little or no deformity. In mechanical detail Mr. Fitzgibbon's method offered some advantages; but iron pegs were preferable to silver, as being rigid and efficient, while the silver were flexible.—Mr. WHEELER, having seen the patient before, during, and since the operation, mentioned the result of his observation. The patient having a fracture of the humerus as described, the house-surgeon put up the arm in the usual method with two splints, which were well adapted, and it rested upon a pillow. Next morning the bones, being displaced, were readjusted. The cause of non-union was her indocility and restlessness, wishing to have the splints opened, and not, as Mr. Fitzgibbon had suggested, the want of blood-supply. At the same time, everything except electricity was used to excite inflammation and produce union, so as to avoid operative interference. The operation selected by Mr. Fitzgibbon was that most suitable, and as the result the patient recovered, with every motion perfect except the upward, which was not so perfect as it was before the accident. In his own practice he observed a noteworthy point which he had not seen recorded in the books—namely, that in fracture of the humerus, where there was much immobility, if the bone united, an immensity of callus was thrown out, and that was always on the inner side.—Mr. O'GRADY having operated in half a dozen cases of ununited fracture, said they varied so much in their conditions that no line of treatment in common could be laid down; for instance, the treatment of a transverse fracture of the humerus was different from that of an oblique fracture of the thigh. He had used ivory pegs till it was suggested that the pigs from which the material was obtained might have had tuberculosis, and thenceforwarded he used the plain iron pegs, which were driven by means of the common Archimedean drill with an up-and-down movement. His drill was the one the late Mr. Hutton had. In the after-treatment he adopted the strictest antiseptic procedure—namely, cleanliness and rest, but without the newly-developed paraphernalia.—Mr. CORLEY said there were already nineteen different methods for the treatment of ununited fracture, the large number suggesting that none of them could be regarded as perfect. Mr. Fitzgibbon's formed the twentieth, which he hoped would be perfect. The accident in question—i.e., the non-union of fracture of the shafts of long bones—was of rare occurrence, only one case having come under his observation during twenty years' experience as a hospital surgeon. No doubt, cases arose through the irritability or restlessness of the patient, or want of care on the part of the surgical attendant, pointing to the old adage that "prevention is better than cure." He approved of the ordinary Archimedean drill.—Mr. M'ARDLE mentioned the advantage of using a steel gimlet, with a thread the size of the screw, as giving a hold, and obviating the detritus which Mr. Fitzgibbon's instrument produced. He had used ivory screws, which became loosened sufficiently to draw out.—Mr. TOBIN considered it was an interesting question to determine how long would the screw bite in the bone, seeing that it ultimately loosened.—Mr. FRANKS thought that the method, while ingenious, was rather complicated, and that the surgeon should not be confined altogether to the use of screws. About a year and a half ago he had himself treated a case of ununited fracture of the humerus, the fracture passing through the neck of the bone below the attachment of the capsular ligament. In the first instance, the case had been wrongly diagnosed as a dislocation and put into splints. At the end of six weeks it was sent up from the country to him. He found the lower fragment projecting underneath the skin, which was so extremely thin he feared the slightest movement would send the bone through it. Having decided to remove part of the bone, he exposed it by an incision from the shoulder, and he then removed about two inches of the lower fragment. From the upper one he could take nothing, because it was bound by the capsular ligament. He scraped the bone to revivify it; then, with an ordinary bradawl, he drilled two holes through the head of the bone, passing through the capsular ligament, and two the other way through the lower fragment, and inserted two tolerably thick silver wires, joining and twisting them. Six months afterwards he removed the wires, which, but for the irritation they caused, he would have let remain. Following the operation, he used further antiseptic precautions, with cleanliness and rest. He preferred passing the wires through and thus joining the ununited bones, as being a simpler method than using screws. The less the surgeon trusted to complicated methods and the more he used his fingers the better.—Mr. FITZGIBBON replied. The argument of Mr. Bennett had convinced him of the advantage of steel screw-taps over silver. The grip of the screw was beyond question; for when he thought he had it sufficiently out to remove it with his fingers he had to readjust the brace to extract the last eighth of an inch of it. In the cases alluded to it might have been that the ivory screws being taken from measly pigs produced an amount of irritation and suppuration that would account for the loosening. So far from the brace being a complicated instrument, it

was an ordinary carpenter's tool. To make the hole with a bradawl was objectionable, because of the continuous wabbling backwards and forwards, instead of in the same direction, like the brace. Having seen Hutton and Hamilton operate in ununited fracture, he noticed a great deal of difficulty in getting the wire through the hole in one fragment and then through the hole in the other. But there was no difficulty in introducing or removing the screw-taps.

Mr. P. J. HAYES read a paper on the Treatment of Urethral Stricture by Electrolysis, the comparatively novel method practised by Drs. Robert Newman of New York and S. T. Anderson of Bloomington. He gave the details of three cases in which he had himself adopted the method with encouraging results. Therefore, he strongly advocated the trial of electrolysis not alone in simple cases, but even for the most complicated forms of stricture as calculated to effect unhoped-for benefit, and as not at all interfering with the subsequent employment of other measures, minor or serious. The outcome of the experience of Dr. Anderson, with whom he had had the advantage of direct communication on the subject, combined with his own, indicated that electrolysis was best adapted for the treatment of annular strictures rather limited in length. Having ascertained the situation of the stricture, the tip or exposed metal bulb of an electrode ought if possible to be lodged within it, or, if this was impracticable, the tip must be in close contact with the anterior face of the stricture. Then a small galvanic battery was connected by its negative pole with the urethral electrode, whilst the positive might be attached either to a moist sponge electrode, or, better still, to a thin metal plate covered with moistened chamois leather. The positive electrode would be advantageously applied either to the patient's perineum or against the inner side of one thigh. As to the strength of the current to be employed the patient's own sensations would prove the best guide. The current should be perceived, but it ought not to be pushed to cause pain, nor should the surgeon attempt more than it was needful to effect at each *séance*, using only mild currents and manipulating the electrode with gentleness, and never pushing it through the stricture, as it accomplished more by being allowed to remain in the stricture than by being caused to quickly traverse it. The *séance* might be repeated every ten days if desired. Cauterising would be produced when strong currents were employed, but with mild currents the gradual breaking up of fibroid tissue was effected by a combination of chemical decomposition and vital absorption until but a thin lamella of cicatricial tissue remained to mark the seat of the stricture.—The PRESIDENT: Do you think there is actual chemical decomposition as the effect of the electrode which appears to liquefy the nitrogenous matter—in other words, that the effect is more chemical than physical?—Mr. HAYES: Certainly more chemical than physical. There is probably a combination of both.—Mr. FITZGIBBON said it would be a step in advance if electrolysis proved a permanent cure for resilient stricture.—Mr. TOBIN observed that there was a difficulty of a twofold character which the surgeon encountered—first, to know with certainty whether he was pressing on the stricture, and, secondly, whether it was permeable.—Mr. BENNETT suggested the desirability of taking precautions in directing the action of the current.—Mr. CORLEY indicated the number of false passages in the immediate neighbourhood of the urethra, not one of which could be distinguished from it, and asked would the point of the instrument have the same effect if it went into one of those false passages.—Mr. WHEELER assumed that Mr. Hayes did not propose that electrolysis was suitable for every case of stricture, the procedure being in some to dilate and in others to cut.—Mr. HAYES replied. Encouraged by his own success, he wished to induce others to try electrolysis. In one of his cases there should have been a cutting operation had he not employed electrolysis, which could be done in the majority of cases, and, if ineffective, any other method, major or minor, could be afterwards adopted.

The Section then adjourned until November.

CAMBRIDGE MEDICAL SOCIETY.

AT a meeting held on Friday, July 2nd, Dr. J. B. Bradbury, President, in the chair, the following communications were made:—

Abdominal Tumour of Unusually Large Size.—The PRESIDENT brought forward this case. James B——, aged sixty-two, a labourer, was admitted into Addenbrooke's Hospital on Dec. 16th, 1885, and died on Feb. 20th, 1886. One sister died from cancer of the breast. His present illness began two years ago, with loss of strength, and vomiting, and a swelling appeared just below the xiphoid cartilage. The patient was much emaciated, and complained of distension of the abdomen, but not much pain. There was some œdema of both legs. The abdomen was greatly distended and the veins prominent. The swelling was most prominent above the umbilicus, and there was much bulging in the flanks. A large, painless, uneven tumour could be felt extending from below the ribs to one finger's breadth below the umbilicus in the middle line. The left flank was resonant, the right was dull. There was evidence of fluid in the peritoneal cavity. The upper limit of hepatic dulness was in a line with the nipples. Urine 1027, acid, no albumen; urea 2·8 per cent. A few enlarged inguinal glands on the left side. On Dec. 19th the aspirator needle was introduced in four places over the most prominent parts of the tumour, but only a drop of blood was obtained. The swelling continued to increase in size and the patient gradually became weaker, until towards the end constant vomiting set in and he died on Feb. 19th.—Mr. GRIFFITH gave the following account of the post-mortem examination, which had been made by him. The abdominal cavity was greatly distended with a large tumour, which was so large as to obscure all the viscera from the front, except in the left inguinal region, where coils of the small intestine appeared. This mass was apparently divisible into an upper and left half and a lower and right half by an oblique line running from above downwards and to the left; the former presented a coarsely lobulated, jelly-like mass passing upwards into the left hypochondrium, where it had become slightly adherent to the abdominal wall; the latter was enclosed in a firm, strong, fibrous capsule and closely adherent to the abdominal wall all over the right side. After removal of the mass, the normal relations of the intestine had not been much disturbed. The ascending colon passed upwards behind the mass, being only partially involved in it at the lower part, the small intestine was quite free, so that the tumour had grown in front of the ascending colon and pushed the small intestine to the only free part of the abdominal cavity—viz., the left inguinal region. The stomach, liver, and spleen had all been pressed upwards, carrying the diaphragm before them, and diminishing to a considerable extent the vertical diameter of the thoracic cavities. The mass itself weighed 33 lb., and was soft and jelly-like in consistency. On section it presented the same characters, and in addition large areas of softening and hæmorrhages. Microscopically, the parts near to the seat of hæmorrhages consisted of a very large number of delicate, thin-walled bloodvessels, with small hæmorrhages here and there along their course; between them connective tissue cells, irregular in size, shape and outline, with usually a single nucleus, embedded in a fine reticulum of fibres, besides a few large cells becoming transformed into fat cells. Other parts simply consisted of bands of connective tissue with large masses of fat cells between. All the organs were normal and healthy except the stomach (which was peculiar in being very small and contracted, forming nearly a straight tube stretching across the vertebral column); and the right kidney, which could not be found after the removal of the mass, nor could any trace of it be detected on very careful naked-eye examination. Unfortunately, the right ureter was not looked for and traced upwards to ascertain its presence or absence.—Dr. BRADBURY thought that the tumour was probably a sarcoma of the right kidney, judging from the post-mortem evidence, although there were no symptoms during life, except a small quantity of urine, to point to this conclusion. He found that hæmatura was absent in about half the cases of cancer of the kidney.

Recovery after Fractured Spine.—Mr. WHERRY related a case of recovery from Fracture of the Lumbar Vertebræ, with Paralysis of Legs; and one of recovery after Fracture of the Cervical Vertebræ, with Paralysis of Arms; death occurring twelve years after. Case 1: Charles C——, aged sixty, on Oct. 29th, 1873, fell 57 ft. from a scaffold, and at 28 ft. a plank checked his fall, and lower down he alighted on an office ridge roof. He was nineteen weeks in Addenbrooke's Hospital. A catheter was used for two years; he recovered power in his bladder by degrees, and from his invalid chair began to walk with crutches, and could go a hundred yards pretty well. He had enjoyed fair health during the past thirteen years; now his legs are swollen

and ulcerated. His hands are suffering probably from the crutch palsy. The urine is retained ordinarily, but any beer or tea beyond a most moderate quantity is followed by incontinence. Case 2: Peter H——, nearly twelve years ago, in 1874, was standing on the top of a load of tares and hauling a rope which he thought was fastened down below, when he fell backwards on to the ground. He was in the hospital about a year, and had paralysis of the bladder for seven or eight days only; there was no paralysis of the lower limbs; there were large sloughs on the scapulæ. In carrying him to bed crepitus was felt. His breathing was entirely diaphragmatic. When he had been in bed about a year he began to gain flesh and strength, and sat up in a chair, and later walked about carrying his head erect and his neck stiff. Later he could walk vigorously, but his arms remained paralysed and fixed in the bent position, some slight power of extension was regained in the fingers of the left hand especially, and the upper limb could be moved as a whole a few inches away from the body. There was very little thoracic movement, as indicated by a tape around the chest. After nearly twelve years of excellent health he died thin and anæmic and with a large spleen. The specimen showed the bodies of the fifth, sixth, and seventh cervical vertebræ to be firmly ankylosed; no remains of intervertebral substance between the fifth and sixth, and very little between the sixth and seventh. The coalesced bodies of the fifth and sixth and the bodies above bend forwards so as to make an angle with the bodies of the seventh cervical and upper dorsal. The cervical spine has a marked curve with its concavity forwards. The canal shows a corresponding bend, the angle and the narrowest part of the canal are between the lamina of the fifth and posterior upper edge of the sixth body, an illustration of the usual mode of crushing the cord. The laminæ of the fifth, sixth, and seventh are firmly joined. The articular processes are also firmly united by bone. There is a separation between the articulations of the fourth and fifth, and also, but less, between the third and fourth. The transverse processes of the fifth, sixth, and seventh are closer than natural but not touching; the vertebral artery canal is patens. The intervertebral canal for the sixth spinal nerve is small and irregular in shape, and this cord must have been nipped at its exit from the vertebral canal. The dry specimen showed a general atrophy of the parts damaged, especially the bodies of the vertebræ; and a singular absence of callus.—Mr. WHERRY thought that the brachial cords were pressed upon or damaged at the intervertebral foramina, the spinal cord itself being very little injured. The *main en griffe* was explained by the extensors of the fingers regaining some power, but the interossei muscles remaining quite paralysed. It was hoped that further examination might be made of the wet specimen, which contained the spinal cord and nerves.

Onychogryphosis (*specimen*).—Mr. HYDE HILLS showed two of these nails, of unusually great length, removed from the great toes of a patient.

Reviews and Notices of Books.

Clinical Lectures on the Diseases of Women. By J. MATTHEWS DUNCAN, M.D. Third Edition. London: Churchills. 1886.

THE third edition of this work consists of the contents of the previous edition with the addition of fourteen new lectures and three new appendices, together with a greatly enlarged index. As the previous editions have been already noticed in these columns, we shall confine ourselves to the new matter. The new lectures appear to be those on Endometritis (No. 8), Retention of Menses (No. 13), Amenorrhœa and Vicarious Menstruation (No. 15), Lupus of the Pudendum (No. 22), Polypus Uteri (No. 23), Terminations of Peri- and Para-metritis (No. 28), Terminations of Uterine Fibroids (No. 35), Cancer of the Cervix Uteri (No. 36), Ovarian Cystoma (Nos. 40 and 41), Retroversion of the Gravid Uterus (No. 43), Chronic Inversion of the Uterus (No. 47), Diseases and Injuries of the Perineum (No. 48), and some Minor Ailments (No. 49); and the new appendices those on the Investigation of the Interior of the Uterus by the Carbolised Hand at long intervals after Delivery (No. 56), the Mechanical Dilatation of the Cervix Uteri and the Appliances used for the purpose (No. 57), and Notes of some Experiments on the rate of flow of Blood and some other Liquids through Tubes of narrow diameter (No. 58). The last two are not in any sense clinical lectures, but are experimental inquiries after the manner of many of the author's previously published and collected essays; still we are glad to see them published, even out of their proper place.

The work maintains its character as a healthy and high-toned guide to the practitioner, and indeed in this relation is invaluable. The lecture on Endometritis is a well-timed protest against the conversion of an old disease (cervical catarrh) into a new and fashionable disorder with a long name. The affection or group of affections of the uterine cavity proper known under this name are in a highly unsatisfactory state as regards our knowledge of them, and the title of most of them to the termination "itis" is more than doubtful. The subject of Vicarious Menstruation is also well treated; a recent discussion of the subject left those who deny the existence of such a disorder undisturbed from their position—the position held also by Dr. Duncan. Lupus has been recently dealt with by the author in a series of elaborate papers with excellent illustrations, which will be found in the last volume of the Obstetrical Transactions. The general opinion of the Society seemed to be that the nature of this affection or these affections is open to doubt. For the treatment of polypus the only mode of removal recommended is that by the vulsellum and scissors. It is true that bleeding after this treatment is exceedingly rare, but it is not quite unknown, and the écraseur is, in our opinion, in every respect the best instrument for this operation. In discussing the difficult subject of Hysterectomy for Uterine Fibroid, the author (p. 328) entirely rejects suffering as an indication for operation. This seems to us a mistake. It is true that suffering is not so easily justifiable an indication for operation as danger to life, but to refuse it admission altogether is surely carrying caution too far. No qualification is indicated with regard to the patient's occupation or station in life—an important consideration. One of the best chapters is that on some minor ailments. It is always interesting to read the cream of the note-books of a good observer of large experience. Of the appendices, all are of interest, especially the last two; the last of all (enumerated above) is of especial interest, as bearing on the subject of so-called mechanical dysmenorrhœa.

The least satisfactory lectures are those on Ovarian Cystoma and on Cancer of the Cervix. The latter is occupying, perhaps, more attention at this moment than almost any of the diseases of women, and its operative treatment, as well as its pathology, is making undoubted advances. The present lecture is in these respects not up to date; the practice indicated is not the best now available. In the lecture on ovarian cystoma Dr. Duncan pleads for late operation. In this, in the present condition of ovariotomy, we are sure he is wrong. At the present time the conditions differ widely from those which prevailed a few years ago, before antiseptic surgery was understood. In those days there was far less difference in the risk of "bad" and "good" cases than there is now, for the "good" cases died of septicæmia. Now the "good" cases mostly recover, and the majority of those that die are, we think, complicated cases—that is, cases complicated by twisted pedicle, bad adhesions, suppuration, kidney disease—all of which are, or may be, caused by delay of the operation. In counselling delay we believe that we are counselling great additional risk, and in advising early operation, greatly diminished risk.

Dr. Duncan's style is habitually clear and unaffected, but we would ask him whether, if "time is too precious to permit the survival of such long names as 'corporeal endometritis'" (p. 47), life is not too short for such words as 'pericystomatitis' and 'endocystomatitis'" (pp. 378-9).

It merely remains for us to express the gratification that most of the additional work has given us, and to strongly recommend it, as we have done the two former editions, to medical readers.

History of the Royal College of Surgeons in Ireland and of the Irish Schools of Medicine; including numerous Biographical Sketches, also a Medical Biography. By Sir CHARLES A. CAMERON. Dublin; Fannin and Co. 1886.

IT is impossible to calculate the time and trouble involved in the compilation of the vast number of references and records which the energy of Sir Charles Cameron has succeeded in obtaining; and too much praise cannot be given for the industry, perseverance, and skilful treatment of the materials at his command. The volume is, indeed, a monument of enduring skill and talent, and its production during his presidential year of office at the College of Surgeons does the author infinite credit. With the space at our disposal it would be impossible to glance at more than a portion of this work, for it contains a complete record of the Irish College and a general summary of the history of medicine in Ireland, with biographical sketches of many eminent physicians and surgeons.

The annals of Tiernach are, with the exception of the Psalter of Cashel, the oldest Celtic manuscript, and it is stated in them that in the year 366 a princess died from having swallowed a *poisoned draught*, from which it may be inferred that even in that early age some knowledge of the preparations of drugs prevailed. Legendary lore assigns to the ancient Irish a high degree of surgical skill, and it is mentioned in an ancient manuscript that Josina, the son of a Scotch king who reigned about a century and a half before the birth of Christ, was sent by his father to Ireland to be educated among the physicians and surgeons of that country. In the libraries of Trinity College, Dublin, and the Royal Irish Academy there are large collections of manuscript works on medicine written in the Irish language. Many of them are dated in the fourteenth century, and the caligraphy of several of them is quite equal to anything of the kind met with in monastic manuscripts. Epidemic influenza is first described in an Irish manuscript of the fifteenth century under the names of *fuacht* and *sloudhan*. That medical men occupied a definite position amongst the Irish from the sixth to the fourteenth century is evident from the clauses referring to them in the Brehon, or Irish code of laws, and about 1000 years ago it became the practice in Ireland to adopt medicine as a hereditary profession. There were very few books published in Ireland during the sixteenth century, and there is reason to believe that the first medical work by an Irish author which appeared in type was Dr. Anguilbert's "Mensa Philosophica," published in Paris in 1530. Dr. Thadeus Dun practised in Switzerland and published in 1591 his "Epistolæ Medicinales," and was probably the first to suggest the use of the warm bath in tedious labour. The first medical work printed in Dublin was by Dr. Dermod O'Meara in 1619. Other authors of medical works were numerous, and include the names of O'Glacan, O'Connor, Stearne, Temple, Molyneux, Mullin, Patterson, Boyle, Greatrakes, Bellon, Allen, Bryan Robinson Rutty, Cope, Cheyne, Lucas, Hopkins, Silvester O'Halloran &c. The last-named in his writings shows that Petit was not, as generally supposed, the first to extract an opaque crystalline lens, that operation having been described by an Arabian physician, Jesus Hali Arculanus, and other ancient authors. O'Halloran was also the first writer who demonstrated that trephining was unnecessary in certain cases of depression of the bone; and was the first to perform amputation of the thigh by a long anterior flap and a short posterior one, formed by a circular division of the soft structures. In former times physicians, as a rule, were graduates of universities, while surgeons learned their art just as the goldsmith or the tailor, by an apprenticeship to a master; hence the surgeons were classed with the higher ranks of tradesmen and the physicians with the members of the liberal professions. This is the reason why surgeons did not receive until after their incorporation into a Royal College the title of "Esquire." On October 18th, 1446, King Henry VI. established by Royal Charter a Fraternity or Guild of Barbers. The Dublin fraternity were styled simply barbers, but "barber" was the exact equivalent for "surgeon" in those days. The Charter of King Henry enabled women to be admitted to the freedom of the guild—a proof that even in those early days women aspired to be disciples of Æsculapius. Queen Elizabeth's Charter was granted in 1572, and the third Charter was given to the Dublin surgeons in February, 1687, in the reign of James II. The Charter granted to the King and Queen's College of Physicians in 1692 prohibited any person practising medicine in Dublin, or within seven miles of that city, without a licence from the College; yet many graduates of British and foreign universities practised in Dublin, and were never licensed by the College. From the close of the seventeenth century the barber-surgeons appeared anxious that the members of the different crafts should keep to their special calling. Members belonging to the barbers' crafts were restrained from practising surgery, except bleeding or the drawing of teeth; and the medical barbers and the wig-makers were, under pains and penalties, prevented from practising pharmacy. A Charter granted by George II. incorporated the Dublin apothecaries into a guild, dedicated to St. Luke, and in 1792 an Act of Parliament constituted the apothecaries into the corporation of the Apothecaries' Hall, which still exists. In 1784 the union between the barbers and surgeons was dissolved *de facto*, though perhaps not *de jure*, by the creation of a Royal College of Surgeons in Ireland; and the Irish surgeon's privileges were no longer confined within the narrow boundaries of a civic trades' union, but he became a constituent of a national institution. The Barber-Surgeons' Company were, however, not dissolved, nor were they expressly forbidden to continue styling themselves the "Fraternity of Barber-Chirurgeons."

It is evident that there were very few opportunities of studying anatomy in Ireland up to the middle of the last century, and the instruction in the medical school of the University of Dublin appears to have been confined chiefly to professorial demonstrations. That the College of Physicians occasionally claimed the bodies of executed persons is shown by some records of that institution. An account-book, beginning in 1672, mentions the items of expenditure incurred in connexion with the dissection of a body. The total is £2 4*s.* 10*d.*, of which 9*s.* was given to the "souldiers who watched," and 3*s.* to "the said souldiers in drinke." Robert Hoyle was the first anatomical lecturer in Trinity College, and was succeeded by Bryan Robinson, an eminent *physician*.

The office of State Chirurgeon, or Surgeon, was created by patent on July 1st, 1774, the first State dentist was appointed in 1821, and the first State oculist the following year.

The first purely surgical examining board in Ireland was created under the provisions of an Act of the Irish Parliament, passed in 1765, establishing county infirmaries for the reception of poor persons suffering from non-infectious diseases, or diseases requiring surgical treatment. The Act provided that no surgeon should be appointed to a county infirmary unless he had been examined and certified to be competent by a board of surgeons. The board consisted of the surgeon-general and the surgeons to Steevens' and Mercer's Hospitals for the time being. On Sept. 1st, 1766, the first candidates were examined in the following subjects: anatomy, including osteology, myology, angiology

neurology, and splanchnology; surgery, including wounds, fractures, and dislocations, tumours and ulcers, operations of the head, trunk, and extremities; and chirurgical pharmacy. The fee for examination was £1 2s. 9d. In 1791, the board passed a resolution in favour of transferring their powers to the College of Surgeons. On March 29th, 1780, a number of surgeons constituted themselves into the "Dublin Society of Surgeons," and having applied for a Charter, they obtained it in February, 1784, and their corporation was entitled the Royal College of Surgeons in Ireland. The College consisted of a president, six censors, and twelve assistants, Samuel Croker King being the first president. By the terms of this Charter all members of the College, so long as they practised surgery, were freed and exempted from the several offices of constable, churchwarden, and all other parish, ward, and leet offices, and from serving upon any jury or inquest in any county, city, or town in Ireland. The first meeting of the College, we may add, took place, in the Rotundo Hospital, the great maternity founded by Bartholomew Mosse. Before the establishment of the College of Surgeons, it was unusual in Ireland for physicians to meet surgeons in consultation, but in 1785 the College adopted the report of a special committee, recommending in the interest of the public that the members of the professions of surgery and physic should reciprocally consult together. In 1789 the College acquired premises in Mercer-street, and in this year the income of the institution was only £65 8s. 3d. In 1805 it received a grant of £6000 from Parliament, and in the same year an agreement was entered into for a new site, in the position in which the College now stands, and which previously was a cemetery belonging to the Society of Friends. The foundation stone of the new buildings was laid on March 17th, 1807, and a grant was obtained the same year of £4500, another in 1808 of £9517, and the same year a further grant of £5300.

Sir Charles Cameron's book, which contains 759 pages, is a large and handsomely got up volume, the type being remarkably good; and its perusal will be of interest not only to the medical profession, but to the community at large.

OUR LIBRARY TABLE.

Materia Medica: a Manual for the use of Students. By ISAMBARD OWEN, M.D., F.R.C.P., Assistant-Physician and Lecturer on Materia Medica at St. George's Hospital. Second Edition. London: J. and A. Churchill. 1886.—We have much pleasure in recording the appearance of the second edition of Dr. Isambard Owen's Materia Medica. It has no pretensions, as the author states, to be considered an original or complete treatise on the subject, and is simply intended to aid students by placing before them the main facts in such a manner that they may be clearly grasped and readily committed to memory. In the present issue a chapter has been added on the "medicinal uses" of the Pharmacopœial drugs, a subject on the accurate knowledge and understanding of which great stress is now laid by the various examining boards. Dr. Isambard Owen has performed a difficult task with discretion, and his work is deserving of much praise.

A Practical Treatise on the Sputum. By G. HUNTER MACKENZIE, M.D. Edinburgh and London: W. and A. K. Johnston. 1886.—The impetus given to clinical microscopy by the discovery of micro-organisms specific to such diseases as pneumonia and phthisis is reflected in this work, which is the outcome of much original observation, and is very well worthy of perusal. We note that the pneumococcus is not held to be distinctive of pneumonia, and a case of pulmonary congestion and hydrothorax is given where it was present. The value of elastic tissue in the sputum as diagnostic of acute phthisis is shown to be over-estimated, but the bacillus tuberculosis was found by the author in all but eight out of a total of 100 cases of phthisis, these eight cases including four of chronic phthisis, where bacilli are notoriously few or even absent. The work contains also a study of the sputum in laryngeal disease, and some striking examples of the value of this research in tubercular and malignant affections are given. Two chapters are devoted to therapeutic indications, the results of climatic treatment and of local and general medication upon the tubercular bacilli being of especial interest. The work is admirably illustrated by numerous coloured plates, and full directions are given for the methods employed in the examinations.

Contra-indications for Visiting the High Altitudes, with a Description of the Environs of Maloja, Upper Engadine. By A. TUCKER WISE, M.D. Pp. 22. London: Churchill. 1886.—This is a reprint of about four pages of the author's work entitled "Alpine Winter in its Medical Aspects," which relate to the class of patients who should refrain from seeking health at high elevations. The remainder of it, on the summer attractions of the neighbourhood of the Maloja, is also taken from the same work, with some useful additions. The *brochure* is evidently intended not for the profession, but for the class of persons who resort to Switzerland in search of health, and to them it may prove useful as a guide-book. We cannot, however, but regret the insertion at the end of the pamphlet of four pages of laudatory notices of the author's "Alpine Winter," reprinted chiefly from newspapers.

The Therapeutics of Hydrophobia. By Brigade Surgeon WILLIAM CURRAN.—This readable pamphlet contains a variety of information, chiefly of the amusing order. "Touching the measures or media that have been so much lauded or relied on in this connexion, they vary so much as to imply, by that variation, that they are quite worthless. They include every wild herb, insane root, or shocking substance that Dioscorides described or Pliny portrayed, and they range from adders' tongues and 'a bit of the dog that inflicted the bite' to the 'scrapings of a tin kettle or of a pewter pot.' Men and women, too, have been cupped or cauterised in pursuit of this phantom till their flesh fizzed like a rasher on a gridiron; they have been bled or blistered for it till they fainted away, or looked as red as a rose or as blotched as a boiled lobster."

Proceedings of the Medical Society of London. Vol. VIII. London: Harrison and Sons.—This volume contains the following valuable papers, among others:—Sir Joseph Lister: On Corrosive Sublimate as a Surgical dressing. Dr. Kingston Fowler: On Functional and False Murmurs. Dr. Markham Skerritt: Conduction of Physical Signs in Diseases of the Lungs. Sir Andrew Clark: Relapsing Pneumonia. Dr. S. West: Case of Aphasia, with lesions about the angular gyrus. Mr. Henry Morris: Surgery of the Kidney. Dr. Beevor: Paralysis Agitans without Shaking. Dr. Coupland: Malignant Endocarditis. Dr. Ord and Dr. Semon: Note on Laryngeal Paralysis in Locomotor Ataxy. Dr. H. Bennett: Brachial Monoplegia from lesion of internal capsule.

Outlines of Infectious Diseases, for the use of Clinical Students. By JAMES W. ALLAN, M.B. London: J. and A. Churchill. 1886.—This little book bears evidence of having been carefully compiled, and its author's position at the Glasgow Fever Hospital entitles him to write with authority. Dealing with the salient features of the leading infectious diseases, it conveys considerable information within a small compass; and being both concise and accurate, it should be of considerable service as a guide to students.

The Dublin Journal of Medical Science. March, 1886.—The original communications of the current number are—(1) Therapeutic Uses of Digestive Ferments, by Dr. Purser; (2) A Case of Spina Bifida treated by Excision, by Dr. Thomas Sinclair; (3) The Poor-law Medical Charities System of Ireland, by Dr. Jacob; (4) Goitre in the Himalayas, by Brigade-Surgeon Wm. Curran; (5) Experimental Researches upon Tuberculosis and Scrofula, by Edwin Wooton.

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 4, 1886.

James Goodchild Wakley, M.D.

In Memoriam.

IT is a happy dispensation of nature that sorrow is not a communicable evil from one person to another. And yet we feel sure that the deep personal sorrow in which we who are immediately connected with THE LANCET are this day plunged will touch the kindly sympathy of our readers all the world over as they learn that, under the disposing will of GOD, the chief directing hand connected with this journal is for ever at rest.

We cannot in these columns, at this moment, speak at any great length of him whom we knew so well, and whose active and useful sphere of human labour is now closed. We should feel it best to be most reserved, under the cloud of sadness which naturally oppresses us, at such a solemn moment; but we may with confidence say a few words respecting our late chief beyond what is merely biographical, and beyond what we could have ventured to have said while yet he lived.

No one exercising an important public post, and exerting through it a daily living influence on the profession of medicine, was ever more retiring from professional social life than the late Dr. WAKLEY. His father, the founder of THE LANCET, was essentially a public man; he was met in all circles, and enjoyed as much as anyone the life of society when it did not interfere with the duties pertaining to his laborious undertakings. But JAMES WAKLEY cared for none of these things. Punctual to his daily tasks as man could be, watchful over every line and word that was to be published under his direction, industrious in the steadiest sense of the word, he was only too happy, as the weight of each week's work was removed, to escape from the scene of it, and in country life, away altogether from the bustle of society and the arena of dispute, divert himself in his own way until the time came for him to be once more at the desk. This pronounced taste has had a remarkable effect on the tone of THE LANCET since it has been under his exclusive leadership. It qualified the intensity of the fire of the journal, while it kept the fire genially alive. A man so retiring escaped the danger of personal conflicts, and was enabled to treat the disputes of others, which came officially before him, with such fairness and goodwill that during the long period of twenty-five years of editorial responsibility no touch of rancour or personal injustice can, we believe, be discovered on any page. In addition, Dr. WAKLEY possessed what was essentially a gentle nature visible always when the little storms which sometimes disturbed it had passed away. The unsparing rod wielded by his father against all enemies, and the sometimes too great admiration extended by his father to attached friends—extremes which are so commonly marked in men of the most powerful order,—were extremes unknown in him. He is supposed, indeed, to have erred more than once in the opposite direction, and, from desire not to inflict pain, to have sometimes permitted editorial criticisms to fall perhaps too lightly. Some may have considered this a fault in an editor, but if so, it was a fault prompted by kindness, easily forgiven, and often too easily forgotten. In other respects he was, by instinct and training, every inch an editor. He did not write much himself, but he was skilful and keen in discovering men who could write, and what they could write; and he read every line that was written by his staff in which there was anything controversial with the most scrupulous nicety and supervision. He was bold in exposing evils of a general or public character; hearty in helping forward every public advancement; zealous to make THE LANCET the first chronicler of any new and promising progress in the science and art of medicine; and specially anxious to make it useful in works which were of a sound philanthropical and beneficent nature. His action in the investigation of abuses in the workhouses of the kingdom, and in the Metropolitan Hospital Sunday movement (his interest in which was recently strikingly shown by the suggestions he made for increasing the amount annually received) is sound proof of his generous nature as a public servant, teacher, and benefactor.

To say that he was fond of THE LANCET is to express a fact which everyone can understand. He loved it, and he lived for it. He was just old enough to remember through what struggles and difficulties THE LANCET had passed before it reached the commanding and successful position it had attained when he accepted the responsibility of conducting it. To succeed a man whose extraordinary strength of will, and power for the exercise of that will, were supplemented by acknowledged genius, was no light matter; and none knew better than Dr. WAKLEY the onerous risks involved in the task. He approached the labour determined to do his best, and if we, his successors, succeed in doing as well as he did, we shall, we trust, when the time comes, lay down the pen with equal resignation to the Supreme decree, and with equal hope of having helped to advance, in our sphere and to the best of our limited capacity, the comfort and happiness of our fellow-men.

SINCE the almost simultaneous discovery in 1868 by NEUMANN of Königsberg and BIZZOZERO of Turin of the fact that bone marrow contained nucleated red blood-corpuscles, there have been many and repeated observations made upon this tissue with the view of establishing it as one of the main hæmopoietic organs, and of ascertaining how far it is affected in disease. The history of these researches is given by Herr GEELMUYDEN of Christiania, in a paper he has contributed to VIRCHOW'S *Archiv* (Bd. 105, Heft. 1), to which we may refer those interested in tracing such historical lines. But it will suffice here to follow the author along the course of his personal observations, which bear evidence of being as carefully made as they are clearly and succinctly stated. His purpose was to ascertain whether in disease the bone marrow undergoes any macroscopical or microscopical changes, and to study the various cell forms found in it, so as to ascertain how far the manufacture of blood-corpuscles takes place in this organ after the period of growth. Now it is well known that the marrow of the long hollow bones—e.g., the femur—differs from that filling the spongy tissue of such bones as the ribs, sternum, and vertebræ. It is a difference not only in colour—the one being yellow, the other red,—but also in constitution—the former being largely fatty, the latter mainly composed of lymphoid tissue. It is in this lymphoid marrow that we may expect to find the hæmopoietic function seated, and its structure seems to denote this. It contains cells of various sizes, mostly rounded, and with a homogeneous or granular protoplasm. There are coloured nucleated corpuscles, some of which have more than one nucleus, but how such bodies became converted into the non-nucleated red corpuscle is not certainly known. Then there are the multi-nucleated myeloplaques, together with spindle-shaped and stellate cells, and pigmented cells—some of which contain red corpuscles embedded in their substance. Red corpuscles also abound, and fat-cells to a certain extent. In the fatty marrow which occurs in long bones there is little else but adipose tissue traversed by thin-walled bloodvessels, the variegated redness which is to be met with depending on the greater or less engorgement of these vessels, which readily rupture. The red or lymphoid marrow in certain conditions replaces the yellow or fatty, and, as just stated, exists always in certain spongy bones; and, histologically, it is composed of a framework of delicate connective tissue, sustaining thin-walled capillaries and vessels, which are surrounded by the cells above described, but with hardly any fat cells. In certain wasting diseases, such as cancer and tubercle, the fat disappears from the marrow of long bones just as it does from other parts of the body, and, not being replaced by any lymphoid tissue (as it is in pernicious anæmia), results in the conversion of the marrow into gelatinous material by mucoid change. Thus there are three varieties of bone marrow—the lymphoid, which occurs normally throughout the skeleton in fœtal life, and limited to spongy bones in adult life; the fatty, which fills the shafts of all tubular bones; and the gelatinous, which results from the degeneration of the latter. In certain diseases there may be a reversion of the fatty marrow to the lymphoid in the long bones.

It becomes, therefore, interesting to know under what morbid conditions the fatty marrow undergoes this conversion, and to that end the author has made many observations in disease, and collected recorded facts which he has embodied in an instructive table. He here gives in percentage the proportionate number of cases of various diseases in which the marrow of long bones presented the normal fatty condition and the abnormal lymphoid state; whilst, in parallel columns he has also placed the proportionate occurrence in the marrow of spongy bones of nucleated red corpuscles and pigment cells, indicative of blood formation. He thus contrasts cases of healthy individuals, killed by accident or in other ways, with cases of local disease and pure uncomplicated anæmia, as well as diseases in which there has been a general defect of nutrition—the secondary anæmias, so-called. To select only a few. The percentage of cases in which fatty marrow occupied the hollow bones was, in health, 100; in heart-disease, 83; in serous inflammation, 83; in anæmia from hæmorrhage, 83; in pernicious anæmia, 18; in Bright's disease, 100; in amyloid degeneration, 69; in cancer, 59; in chronic tuberculosis, 43. Lymphoid marrow was found in these bones in the following percentages: Heart disease, 8; serous inflammation, 17; pernicious anæmia, 82; amyloid degeneration, 6; cancer, 8; chronic tuberculosis, 13. Lastly, the gelatinous marrow occurred in 8 per cent. of the cases of heart disease, in 25 per cent. of those of amyloid degeneration, in 33 of cancer, and in 43 of chronic tuberculosis. Of diseases of the œsophagus, stomach, &c., which induce inanition, 80 per cent. yielded fatty marrow and 20 per cent. gelatinous marrow in the long bones. The most striking fact in these figures is the very high proportion of cases in which lymphoid marrow replaces fatty marrow in pernicious anæmia.

The reason why there should be this remarkable conversion of medullary tissue in such a disease as pernicious anæmia has been the source of considerable speculation. If the lymphoid form of marrow is concerned in the manufacture of red corpuscles, the only feasible explanation is that the change is of a secondary or compensatory kind, to make up for the corpuscular destruction to which the anæmia may be ascribed. Further support of this is found in the extremely large proportion of nucleated blood-corpuscles found in the marrow in this disease, indicating, it is conjectured, an increased activity of blood cell formation. It is true that COHNHEIM interpreted the presence of these nucleated corpuscles in another way—viz., that owing to defect in the formative process, the corpuscles remained in an immature embryonic state; but this view does not meet the question of the remarkable substitution of inert fatty marrow in the hollow bones by the active lymphoid tissue. Moreover, this substitution occurs, although to a less degree, in many other diseases which are characterised by anæmia, depending on loss or waste of blood constituents. In leukæmia the marrow is found to undergo hyperplasia similar to that which affects other lymphoid organs, and there is one case recorded by LITTEN where leukæmia developed on pernicious anæmia. This, however, is the only instance where a true hyperplasia has been found in pernicious anæmia, so that the phrase "medullary pseudo-leukæmia," applied to this disease, is a misnomer. A further peculiarity of bone marrow in pernicious anæmia is the frequent presence therein of large cells containing blood-corpuscles and pigment, suggesting that destruction as well as regeneration of corpuscles

goes on in this tissue. It must not be supposed that this is the efficient cause of pernicious anæmia, for the same appearances are to be found in cases where the anæmia is less permanent. On the contrary, the presence of these corpuscle-holding cells is more likely due to the peculiar condition of the circulation in the marrow, rendering hæmorrhages more liable; and when to this is added the special proclivity to hæmorrhage that characterises pernicious anæmia, the presence of such cells and of pigment in excess is accounted for.

GEELMUYDEN has also examined the blood-forming organs (especially the marrow) of frogs, toads, newts, fowls, rabbits, and kittens, with the object of tracing the development of the red corpuscle. His research here was not very profitable, but in a few instances he obtained evidence of the division of blood-corpuscles (as in the frog's spleen), and of transitional forms between the colourless marrow cells and red corpuscles (as in the fowl). Although we cannot think that much advance has been made by this contribution, it has no small merit of clearly defining the aspect in which the bone marrow as a hæmopoietic organ should be regarded; whilst the statistics supplied as to the changes undergone by the marrow in disease may afford a valuable starting-point for further investigation. It is now hardly disputed that bone marrow is concerned in blood formation, but it is still undetermined to what extent this function is performed during adult life, and in particular are we as yet ignorant of the precise pathogenic history of progressive and so-called "idiopathic" anæmia.

THE term "spaying" is one whose meaning is well understood generally by medical as well as non-medical persons. It has this great advantage, as is pointed out in our columns this week by Dr. GRIMSDALE. As practised in this country upon animals, the operation consists in the removal of the ovaries and Fallopian tubes, or uterine appendages. Objections have been raised to the term on grounds which are untenable. An operation should be named not by reason of the motive with which, or the purpose for which, it is done, but according to its nature from an anatomical point of view. In England spaying means removal of the uterine appendages, and castration the removal of the testicles, with whatever motive or for whatever purpose such organs are excised. In Germany there is but one term, "castration," for the two operations, and "castration der Frauen" is the phrase used for the removal of the uterine appendages in the human female, and is the equivalent of the English phrase "spaying of women." When BATTEY proposed the removal of one ovary in the human female for certain suffering, he suggested the term "normal ovariotomy" for the operation, because it consisted in the removal of an ovary still functionally active. This is not spaying, and the word "spaying" would have been inapplicable to it, for the word means removal not of one but of both ovaries. It was, however, soon discovered that the removal of one ovary was insufficient, and that if operations for the removal of active ovaries were to be performed at all, both glands should be removed in every subject. Now the term "spaying" became appropriate, and the only appropriate English word for the operation, and intelligible to everybody. At this juncture Dr. MARION SIMS proposed the expression "Battey's operation," and it was adopted, but in a half-hearted sort of way. Mr. TAIT calls the operation "removal of the uterine appendages," a phrase to which there can be no objection on anatomical grounds, but which is clumsy when compared with the single and expressive word "spaying," and has at the same time the disadvantage of being quite unintelligible to all except scientific persons. Some Americans have called it "Tait's operation." Three surgeons claim the discovery of this innovation: BATTEY in America, TAIT in Birmingham, and HEGAR in Germany. The operation has been called after the first two by some, both in England and in America, but no such folly has been perpetrated in Germany. There the term "castration" is applied to the operation, and no patient can mistake what it means; and with such an expressive English word as "spaying," understood of all a word which was used for the operation before BATTEY, TAIT, or HEGAR thought of performing it in the human female,—with such a word for our use, it would be ridiculous and absurd to use a long phrase to designate it. We can conceive no objection to the word "spaying," but the patient upon whom the operation is to be performed should clearly understand what she is really about to undergo.

A CONSTANT current of electricity passing through a length of nerve causes a contraction in the muscle to which the nerve belongs only on making and breaking the circuit, or when the intensity of the current varies. The faradaic current, or rather series of shocks, causes a state of continuous contraction called tetanus. It is conceivable that a certain kind of nerve impulse might cause a continuous contraction of a muscle. As we cannot induce this by any known means, there exist sufficient reasons for doubting whether Nature works after this fashion, or whether she does not act in conformity with known principles. Most probably there is a series of impulses traversing the motor nerve when a voluntary contraction takes place—that a muscle then is thrown into a state of tetanus. Direct evidence of the tetanic nature of a voluntary muscular contraction has hitherto been wanting. The evidence on which the opinion is based, that the contraction is discontinuous, is by no means of a conclusive nature. It is asserted that a muscle contracting under the influence of the will gives a sound, of musical quality, composed of a definite number of vibrations caused by a corresponding number of muscular twitches fused into the tetanic contraction. This conclusion was apparently supported by the fact that the sound emitted by a contracting muscle corresponds, as far as can be made out, with that of a vibrating metallic reed or tuning-fork which is employed to interrupt a galvanic circuit stimulating the motor nerve. The first sound of the heart is almost certainly the product or accompaniment of a single act of the ventricular contraction, and yet this sound has the same characters as the muscle contracting under a volitional impulse. It has also been shown that the muscular note of voluntary contraction is not constant, but varies with the tension of the muscle. The note heard from a voluntarily contracting muscle consists of thirty-six to forty vibrations per second, but it is doubtful if this is any guide to the rate of muscular response. The experiments of HELMHOLTZ showed that the vibrations of the muscle were only about half as

numerous as the number of vibrations in the note heard. He also pointed out that the muscular note is the resonance-note of the ear, and is capable of variation by merely modifying the resonance of the ear, as by performing VALSALVA'S experiment. The employment of the myographic method for demonstrating the discontinuity of the voluntary muscular contraction has in the hands of Mr. A. E. SCHAEFER, with the assistance of Messrs. CANNEY and TUNSTALL, proved of great service.[1] The conclusions of the authors are: 1. A prolonged voluntary contraction in man is an incomplete tetanus produced by eight to thirteen successive nervous impulses per second. 2. The average rate of muscular response to volitional impulses is approximately the same in man and many other mammals. 3. The average rate of muscular response to volitional impulses is the same approximately as the average rate of muscular response to rapidly recurring excitation of the motor nerve centres in animals. The average rate of muscular response to volitional stimuli in man is approximately the same as that obtained both in man and animals as the result of that excitation of the cerebral cortex that causes epilepsy (with explainable differences.) Further, the rate of muscular response to volitional stimuli in man is nearly the same as the rate of muscular response evoked by activity of the spinal cord alone.[2]

Annotations.

"Ne quid nimis."

CHOLERA IN SOUTHERN EUROPE.

CHOLERA continues to exhibit a further abatement in Italy. During the week ending August 31st, the recorded cholera deaths amounted to 227, as opposed to 318 in the week immediately preceding. There is also an absence of any further intelligence as to cholera from the Austro-Hungarian Empire. Reverting to Italy, it is noteworthy that the severe outbreak at Barletta, which at one time caused upwards of sixty deaths a day, is so far at an end that for several days during the past week the total daily cholera mortality has not exceeded one single death; and at the same time the only newly infected place in Southern Italy as to which statistical information has been received is San Giovanni Rotundo, close to San Marco in Lamis, which was first included in the mortality lists in the preceding week. But whilst this is the case, intelligence is received to the effect that cholera still holds its sway in Southern Italy in a large number of small villages, records from which are not transmitted abroad, and the *Roma* publishes a long list of those places where the disease still prevails. The outbreak in San Giovanni Rotundo is severe. The place has only some 8000 inhabitants, and over 100 have already died of the disease; indeed, in the last two days of August the attacks numbered forty-six and the deaths nineteen. The sanitary state of the town is spoken of as being very bad indeed; many of the inhabitants living in so-called grottoes, which, as a rule, are densely-crowded, underground apartments shared by members of more than one family. They are spoken of as "stables of human beings." In North-eastern Italy a decided abatement of the disease has taken place, and although records are still received declaring the prevalence of cholera in many localities, yet the low rate of deaths to attacks in some towns justifies the caution which has been issued as to regarding all the cases referred to as genuine cholera. But, on the other hand, the mere fact that this low mortality prevails here and there cannot do away with the inference to be drawn from the persistent prevalence of so fatal a disease as that which still obtains in such towns as Ravenna. In that place there were eighty-nine attacks and fifty-seven deaths in the last week of August, and we are not aware of any disease which can persistently week after week cause so large a mortality as this, and which can be continuously mistaken for cholera. Associated as the outbreak is with unquestioned cholera in the south, it is evident that this same disease prevails further north, although in some places fatal diarrhœa or some other allied disease may be included in the returns of cholera mortality.

FRANTIC PHYSIOLOGY.

WE have not a word more to say on the subject of "fasting" girls and men, whether the agent of self-control in the process of starvation be hysteria or a morbid longing for notoriety. These performances ought to be put down, or, if that cannot be accomplished without undue encroachment on "the liberty of the subject," discountenanced by the press and public opinion. We hold it culpable on the part of the newspapers to lend their columns to the support of these wanton exploits, even in the season when, as the *Saturday Review* once put it, "everything persists in not happening." What if it be possible to fast forty days and forty nights, where is the good of the achievement? The practice of abstinence carried thus far is scarcely likely to be of any practical use except to shipwrecked sailors or travellers in the regions of extremely bad cooking; and even in the face of such contingencies as may occur to the classes of society thus exposed, starvation will not, we venture to predict, be developed as a fine art. Meanwhile it is encouraging self-injury, if not actually self-murder, to countenance wanton risks of any sort, whether by voluntary starving in the midst of plenty, or by trying to "shoot Niagara" literally instead of metaphorically. There is, however, a phase of the sensational starving system in respect to which it does seem necessary to say a few plain words to physiologists who appear to be in danger of losing their heads scientifically. It is, we cannot help thinking, a peculiarly profitless, and may readily be made a mischievous, enterprise, to patronise the attempt to reverse the order of Nature by perversely and persistently refusing to satisfy her demands. The policy of the day in dietetics is confessedly one of "doing without" things. There may be reason in doing without certain creature comforts which habit has almost dignified with the character of necessaries, though even this abstinence may be carried too far, inasmuch as the whole question of necessaries and superfluities is one of *relativity*. For example, if we take certain forms of food, it is better to take therewith appropriate condiments. Even so simple a matter as roast beef digests, according to Beaumont, something like half an hour quicker with mustard than without. It is desirable to recognise this relativity, and to abstain from quoting absolute laws to interpret the working of relative processes. Apart from this, and strictly within the limit of plain facts, it is *not* desirable to waste scientific strength and time in the pursuit of phantoms. We do not need to know precisely how far the refusal of food may be pushed without causing death. Nothing would be gained by such knowledge, and it is a scandal to science that physiologists here or on the Continent should express or betray the slightest interest in such vagaries as those which are again in peril of becoming fashionable. It would seem needless, though in fact it is necessary, to remind the quasi-medical public that it is perfectly well known that coca leaves chewed with lime

will so deaden the nerves of taste, and probably those of digestion also, that the organic need for food is not felt, and that by this practice the natives of certain districts do actually abstain from food for days together, particularly after eating so large a meal as to emulate the Greenlander's thirty-three pounds of blubber. It is probable that there are several varieties of leaves which will answer the same purpose as the coca. These are not, however, valid reasons why there should be a revival of the folly of starving for weeks together, and against this or any similar sensation, whether by the chewing of leaves or roots, or the drinking of infusions, decoctions, and elixirs, we most earnestly protest. If such things must be, let men of science and, above all others, medical scientists, show their sound sense in refusing them their countenance, even by the profession of an interest and curiosity which they cannot rationally possess.

TUBERCLE BACILLI AND HEREDITY.

DR. CURT JANI has examined the healthy sexual organs of nine phthisical patients for tubercle bacilli. No bacilli were found in any of these cases in the semen from the vesiculæ seminales, but, on the other hand, in five cases out of eight a small number were found in the testicle and in four out of six in the prostate. There was no pathological alteration in the tissue of the testes. Beside these cases, Dr. Jani found in one case of acute miliary tuberculosis numberless tubercle bacilli in the tissue of the prostate. He, further, examined two women who died of pulmonary phthisis, the ovaries both times presenting negative results; in one case of chronic pulmonary phthisis, with extensive intestinal tuberculosis, he examined the tubes and found tubercle bacilli. Dr. Jani is of opinion that the tuberculous poison may pass to the fœtus in two ways—through the semen of the male, and through the migration of the bacilli into the womb from the abdominal cavity. Infection of the ovum after impregnation by the placental circulation he thinks must be unusual, because the examination of the body of a woman, five months pregnant, who died from acute miliary tuberculosis, in whom the general infection took place through the growth of a caseous mass in a pulmonary vein, showed that there were no tubercle bacilli either in the placental attachment or in the lungs, liver, kidneys, or the epiphysial lines of the different bones of the fœtus. Dr. Jani, however, considers that it is by no means certain that in chronic miliary tuberculosis deposits may not form in the neighbourhood of the placenta, and thus infect the fœtal organism.

SEWAGE EXPERIMENTS AT GUILDFORD.

A REPORT has recently been presented to the Guildford urban sanitary authority on experiments made to test the efficacy of Mr. Conder's system for the treatment and purification of sewage by means of certain ingredients, a principal one of which is sulphate of iron. The report states that there are no proper drains in Guildford for sewage, that the whole of the drains of the district have been laid down for surface water only, and that the outfall is to the river. The method adopted which seems to have best succeeded was to construct an open wire-work cage in which the purifying material was placed, and then to let down the cage into the sewer, so that it should be immersed to the extent of about an inch and a half in the flowing sewage, the sulphate being thus dissolved by the sewage without occasioning any impediment. The result is reported to have been a vast improvement in the character of the liquids flowing from the drains into the river, and an abatement of nuisance at points where heretofore nuisance and offensive smells had been complained off. In so far as such results could always be secured, some place more worthy than Guildford might be found to which it should be applied, for, as the surveyor very properly remarks, any benefit to be derived from such a system in that town can only be regarded as temporary, the real need of a proper system of sewerage still remaining. If Guildford must resort to temporary expedients for a while, it may go on with this system with some advantage, but nothing that can be avoided should be allowed to stand in the way of removing from the borough its present reproach as to sewerage arrangements.

DELHI BOIL.

DR. CUNNINGHAM has discovered a peculiar parasitic organism in the Delhi boil ("Scientific Memoirs of Medical Officers of the Army of India," Part I., Calcutta, 1885). The organism in question, brought into view by the use of gentian-violet, was found amidst the lymphoid elements that form the substratum of the boil. The organism is on an average larger than a lymph-corpuscle, but great variations as to size and form were met with—some being circular, others elliptical, others lobate. They contain nuclear-like bodies, which have an affinity for the staining material, and in some specimens present an appearance like that of actinomycosis. The organism occurred in variable numbers in different specimens, and in some were apparently undergoing division. Their most frequent seat was the layer of granulation tissue beneath the papillary layer of the skin; but in places they occurred within the papillæ, and exceptionally even in the epidermis. They were also met with in the subdermal tissue. No definite conclusion as to their nature could be arrived at; but until their life-history can be studied they might be classed provisionally with the Monadinæ among mycetozoa. As to their connexion with the disease, it is obvious, Dr. Cunningham points out, that they cannot gain entrance by a raw surface, since no such condition exists, and the epidermis is abnormally thick and resistant. This very fact, however, suggests the notion of their being causally related to the affection—an idea further borne out by the endemic occurrence of the disease and its connexion with water-supply. It is possible that they gain entrance through the hair follicles and sweat glands, around which the inflammatory changes are most marked and the organisms most abundant. The distribution of the organisms also indicates the need for free excision in the treatment of Delhi boil. "It is quite possible," adds Dr. Cunningham, "that similar changes may be produced by other parasitic organisms, or that the lesions may arise apart from any parasitic agency."

THE INFLUENCE OF MEDICINES ON DIGESTION.

THE rational method in therapeutics is founded on knowledge acquired largely from the experimental laboratory. Any careful investigation in the chemical department of physiology must ultimately prove of value, even though its present effect on practice may be slight or altogether lacking. O. Petersen, of St. Petersburgh, has ascertained the influence of certain medicines on the duration of digestion. The inquiry was of the simplest order, as must necessarily be the case in exact experimentation. The problem Petersen set himself to solve was to ascertain the time required to digest twenty to forty grammes of dried albumen by the aid of 450 c.c. of an artificial gastric fluid made of one gramme of pepsin to a litre of water and ten grammes of hydrochloric acid. Alcohol in the proportion of 5 per cent. did not hinder the digestion, but when the percentage rose to 10 digestion was stopped, whilst first being retarded proportionately before that percentage was reached. Antipyrin, in doses of two to two and a half grammes, exercised no influence on the rate of peptonisation, though larger quantities slightly retarded the action. One or two

grammes of bromide or iodide of potassium hindered the process a little. The organic preparations of iron scarcely affected the time required for the digestion, whilst the reduced iron and the inorganic salts slowed the action. Magnesium and sodium sulphates, even in moderate doses, were in the same case. A gramme dose of chloral hydrate had no slowing effect, though marked retardation occurred with a dose of one gramme and a half. The chloride of sodium, as might have been expected, did not retard digestion, even when employed in large doses.

NOTHNAGEL ON THE TREATMENT OF PERICARDITIS.

PROFESSOR NOTHNAGEL of Vienna, in a clinical lecture on the treatment of pericarditis, advises that in cases where there is pain in the cardiac region, fever, and the commencement of exudation, leeches varying in number from three to ten, according to the gravity of the symptoms and the constitution and strength of the patient, should be applied. The leeches should be renewed every four or six days. Cupping may be substituted, but leeches are preferable. An ice-bag should be applied, or a directing apparatus through which cold water can be constantly supplied to the part. Cold compresses are of no use unless they are laid on ice, and then they must be changed every five minutes. Digitalis for internal use is indicated under certain circumstances. It is useful if the cardiac action is greatly increased, especially if there are signs of the heart muscle becoming implicated, when it should be given in somewhat larger doses. Digitalis is not desirable in the earlier stages of the disease, but in the later ones, when there are signs of weakness of the heart muscle and the pulse is weak, it is indispensable. Other internal remedies are useless. Mercurialisation—viz., calomel in small doses of three-quarters of a grain internally, and grey ointment externally—has no effect. The pain is scarcely ever severe, and if it is persistent it may be relieved by cold and bloodletting. To this a high temperature is no drawback, as the fever subsides as the inflammatory appearances disappear. If effusion has begun, other means must be used such as counter-irritation of the skin and the promotion of reabsorption. Ice and blood-letting are of no use in this case. The cardiac region must be painted with equal parts of gall and iodine tincture, or an ordinary cantharides plaster may be applied, which should be kept on from eight to twelve hours till a blister is raised. This is of greater use in subacute than in acute pericarditis. Digitalis does not directly promote reabsorption, but indirectly by its influence on the action of the heart. Should the patient's life be threatened by copious effusion, paracentesis of the pericardium must be performed. This operation is often employed, and with not unfavourable results. Great care must be observed; the pointed trocar of Dieulafoy's apparatus must not be used, but a blunt one like that of Dr. Fraentzel.

THE SANITARY STATE OF COWES.

AN official inquiry into the sanitary state of West Cowes by one of the medical inspectors of the Local Government Board, and this in connexion with a prevalence of diphtheria, is of especial importance at this time of the year when that place is made a favourite centre for yachting and other holiday purposes. There is, however, no doubt that diphtheria has off and on appeared in the place, and that a recrudescence of the malady has been recently attributed to the prevalence of defective sanitary circumstances. As yet we have not seen Mr. Spear's report, but it is locally stated that he, having failed to attribute the disease to importation or to food supplies, has been obliged to regard it as due to conditions which ought to have been remedied long ago. Offensive emanations from sewers and drains and the lack of a sufficiency of water for flushing and other purposes have for some time past been complained of both in West Cowes and in East Cowes, and it is alleged that the shore is badly contaminated by reason of sewage which passes down the Medina from Newport. We have already pointed out that strong representations have been made to the President of the Local Government Board as to these matters, and since both the medical and the engineering departments of the Board have made local inquiries into the circumstances, it is to be hoped that measures will before long be adopted to remove all causes of unhealthiness and disease from a locality which should be so circumstanced as to attract visitors instead of frightening them away.

IRISH MEDICAL FEES UNDER THE LABOURERS ACT.

WE are glad to notice that after a discussion by the Waterford Board of Guardians, initiated by a protest by Mr. J. B. W. Cane against the existing scale of fees for medical reports on cottage property under the Irish Labourers' Cottages Act, the fee for a report has been raised from 5*s.* to 10*s.* 6*d.* The fee was low enough in all conscience. According to the clerk of the Board, it would not in some cases pay the medical officer's car expenses in doing the work. But, low as it was, it seems only to have been paid in cases where the report was unfavourable. Mr. Cane in his letter said truly that this was an inducement to condemn houses all round. The chairman resisted the payment, and said that the Local Government Board had informed them that the medical officers were bound to give the certificate without pay. He surpassed the Board in unreasonableness by saying that every dispensary doctor who knew his district properly could sit down in his parlour and write down a certificate for any cottage in his district. What prodigiously clever men the dispensary doctors of Ireland must be! One sentence in the report of the Board interests us. The seconder of the motion for increasing the fee from 5*s.* to 10*s.* 6*d.*, said that 5*s.* was a fee that no guardian, even a poor one, would offer to a regularly qualified medical man for visiting his own family. We wish we could say as much for England, which is generally considered the wealthier country. We want to know a good deal more about medical services and their remuneration in Ireland. The motion finally was carried unanimously.

MICRO-ORGANISMS IN UNINFLAMED JOINTS.

THE occurrence of pathogenic micro-organisms in the synovial fluid of inflamed joints due to diseases of different kinds—as, for example, pneumonia, diphtheria, erysipelas, and glanders—having been amply demonstrated by Schüller (*Archiv für Klinische Chirurgie*, Bd. 31, Hft. 2), and no information existing in medical literature as to the examination of the synovia of patients suffering from infectious diseases without concomitant articular inflammation, Dr. Smirnoff of Kazan wished to discover whether in all cases of infectious disease pathogenic schizomycetes migrate into the joints, or whether this occurs only sometimes. He therefore made a series of observations on the bodies of patients who had died of various diseases, but had had no articular inflammation. As a rule the knee-joint was chosen for examination, though in cases of great emaciation from phthisis, where the fluid in the knee was too small in quantity for the purpose, the shoulder-joint was selected instead. It was first carefully inspected to ascertain that there were no signs of inflammation, as redness or swelling. The surface was then washed, together with the knife and the glass

slides required, with a solution of sublimate. A lateral incision was then made, and some of the viscid synovia transferred to the slides and dried. They were then passed several times through a gas flame, and afterwards the preparations were stained with fuchsin, gentian-violet, methyl-violet, &c. and examined microscopically, the observations being in all cases verified by Professor Lubimoff. In five out of nine cases of uncomplicated croupous pneumonia, micro-organisms like Friedländer's diplococci with capsules were found. In two cases of pneumonia complicated with purulent meningitis staphylococci were distinctly recognised. Koch's bacilli were found in three out of eight cases of phthisis. In three cases of recurrent fever (*febris recurrens*), in two of miliary tuberculosis, and in two of Siberian plague no micro-organisms could be detected. Cocci were seen in one case of erysipelas, one of malignant pustule, and in one of frostbitten toes with septicæmia. Three more cases gave negative results—viz., one of burn, one of purulent meningitis, otitis, and caries of the petrous portion of the temporal bone, and one of pericarditis, peritonitis, pleurisy, caseous pneumonia, and perimetritis. The most frequently seen micro-organisms were spherical and ovoid cocci, small bacilli being found much less often, and spirilla and curved bacilli being never seen at all, apparently finding themselves unable to penetrate the joint.

PROFESSIONAL SECRECY AND INSURANCE OFFICES.

THE question of professional secrecy after the death of the patient has been discussed recently in a French court of law under rather peculiar circumstances. A tradesman who was insured in a life office having died, leaving children under the care of a guardian, the insurance office required as a condition for payment of the sum insured to the deceased's heirs a certificate from the medical attendant setting forth the cause of death. This the doctor refused to give, saying that his relations with the deceased were of a confidential nature, and he had received no permission from him during his lifetime absolving him from the obligation of secrecy. The guardian then, who considered of course that he was acting in the interests of the heirs, wished to take the responsibility of absolving the doctor from the obligation to secrecy, but the doctor did not think anyone could so absolve him except the person to whom the secret belonged—viz., the deceased himself. The matter was referred by the doctor to the local medical body, whose opinion coincided with his own, that under no circumstances could he now be absolved from secrecy. The guardian then brought an action against the doctor to compel him to furnish the required certificate. The court, however, found in the doctor's favour, and gave him his costs. The law in France is very distinct on the subject of professional secrecy, assigning a punishment of imprisonment of from one to six months and a fine of from 100 to 500 francs for revealing such secrets, except in the cases where the law requires criminal information to be given; and it applies not only to doctors, but also to "pharmacists, midwives, and all other persons, who by their condition or profession are made recipients of secrets confided to them." This severe regulation has the advantage, it is true, of affording an answer to the importunities of friends or relatives who may be anxious as to the nature of a patient's malady. It might, however, be fraught with troublesome consequences if a patient were to feel aggrieved at its having become known that he had had, say, rheumatism, about which probably the advisability of secrecy or concealment had never occurred to his medical attendant. With us such enactments are relegated to the domain of medical ethics, and we try to act as far as possible in the interests of our patients.

OVERWORK OF TRAMWAY MEN AND OTHERS.

THE pressure of overwork is felt in every calling. With some of those who suffer it is self-imposed and, after a fashion, voluntary. It may be persisted in or repented of in the interest of health or of some convenience more desirable for the time than a gain in money. Quite different is the lot of the large class of over-wrought *employés*. Their labour also is, no doubt, for their own profit, but it is in the circumstances of their case practically involuntary, and their life as we now see it must be lived and ended in a galling harness of paid servitude. The two cases are by no means parallel, though they are sometimes taken to be so. The difference of circumstance is a very important one; and when it is shown, as it has been shown on credible evidence, that the daily term of fourteen to eighteen hours is nothing unusual for barmen, while sixteen hours per day are exacted of tramway men, Sunday rest being as a rule forgotten, and meals, one may say, surrendered to chance, the need of reform must appear to be beyond question. No healthy frame could be guaranteed to stand such a strain for long. The mere standing on the feet day after day for many hours is a tax of endurance of which those who merely witness it can have no due conception. Add to this the petty worries and interruptions of the work, the weather exposure, and the necessarily short allowance of nightly rest, and we have surely more than enough given in exchange for the wages. What becomes of intellectual and moral development it is fruitless to ask. Under all the conditions, and particularly in the face of a liberal turnover, we fail to see that employers, be they companies or persons, are justified in thus blindly enforcing the law of supply and demand with regard to labour. It is to be hoped that even common shrewdness, if no better sense of justice, will teach the careless among us that an early change in the present system is needed, unless the best part of our national vigour is to be needlessly buried in the coffers of invested capital.

THE CONDITIONS OF NEURASTHENIA.

MR. DE BERDT HOVELL has been repeating at Brighton his well-known views on the subject of hysteria. They are to be carefully received as those of a shrewd practitioner of long practice and large experience. He strongly protests against the whole hypothesis of *hysteria*. He thinks the theory that localises the disease in the uterus is the mere survival of medical demonology, which located ill-humour in the spleen, blue-devils in the liver, and the soul in the pineal gland. He claims for hysterical patients more fairness of treatment and more discrimination. He attributes many of the cases to shocks, physical or moral, leading to deficient or depressed nerve-power, with all that this implies in the way of pain, irritability, inability for locomotion, &c. Mr. Hovell admits that the cases are difficult to cure; but he maintains that if we are to deal with them effectually, we must "set aside all consideration of the organs of reproduction, which most probably are not concerned, and transfer our attention to the moral nature." Mr. Hovell gives several cases in which there was a distinct history of shock or exhaustive work to explain the breakdown in the nervous system. We live in days when the nervous system is getting its full share of attention from pathologists and physicians, and when even gynæcologists are finding out that the uterus and even its appendages, which are now blamed by some for everything, are not such culprits as has been supposed. Mr. Hovell will admit that the cases of so-called hysteria do occur chiefly, though by no means exclusively, in women. In their organisation there is *something* specially favouring the occurrence of this state or disease. It may not be in the special organs of the female so much as in the special

organisation of the nervous system. Mr. Hovell deserves much credit for insisting on this point, and he may well be satisfied to know that the drift of opinion among physicians is towards the acceptance of his views. Women are more finely strung than men. They are more liable to pain or pains of all sorts from mere functional causes. Such a constitution is perplexing to the physician, but it has to be considered, and not treated as a sort of crime, as has too often been the case.

THE BIRMINGHAM MEETING AND DIRECT REPRESENTATION.

WE have received several letters on this subject. One correspondent asks why Birmingham should have been selected. Birmingham, we all know, has the reputation of being a place where elections are "worked"; it is the seat and centre of the caucus. This may excite a considerable prejudice against any action of the committee. It is a bold thing, too, on the part of any *one* committee after the British Medical Association has declined action as an association in this matter, to seem to dictate to the practitioners of all England. But there is another side to the question—there is really good committee work to be done. And if there were not to be two or three committees, for which there is much to be said, Birmingham has no slight claim to have a voice in this matter. She contains two practitioners who have done valiant service in this cause. Mr. Sampson Gamgee was the originator of the first great monster petition for direct representation, which remains historical in this matter; Sir Balthazar Foster, during his brief stay in Parliament, had much to do in getting an extra direct representative for the profession. Birmingham will have quite enough to do in deciding which of these gentlemen is to be preferred as a candidate. They both labour under the serious disadvantage of not being general practitioners, but they are untrammelled by official connexion with corporations, and have given noble proof that they prefer the profession to any of its mere guilds. We are in no humour, therefore, to be too hard on Birmingham or on those who selected it, but clearly the movement will require to justify itself by impartiality and breadth of view; any cliquism would be immediately detected and resented. We gather from Dr. Carter's letter that the meeting at Birmingham will be a meeting of the profession in the broadest sense of the word, and will rise above all local or narrow feelings. We accept these representations in good faith.

ETIOLOGY AND TREATMENT OF DIPHTHERIA.

M. DELTHILL of Nogent, in an interesting communication read to the Nancy Congress, gave an account of the results of his method of treating diphtheria by the fumes of turpentine and coal-tar, with local applications of turpentine. Of 134 cases so treated 126 were cured, and prophylactic measures of the same nature being rigorously enforced, only three mild cases of infection occurred amongst 670 attendants. Amongst other observations, he found that the saliva of diphtheritic patients is always acid, that the incubation period is about five days, and that diphtheritic matter which has not been destroyed preserves its infecting power for more than a year; also that the disease may "vegetate in a chronic manner" for several months in an individual. Perhaps, however, the most interesting part of M. Delthill's paper and of the discussion which followed related to the connexion between diphtheria in human beings and epizootic diseases. M. Delthill mentioned the case of a child with diphtheria at a farmhouse, where upon inquiry he found that two months previously to the child's illness the fowls had died of the pip (*pépie*), and that the pigeons had suffered from the same disease. The child had been in the habit of playing in the farmyard where the fowls were kept. M. Bouchard mentioned that he, too, had had a case of diphtheria in a farmhouse near Paris, where all the fowls had died of the pip. He remarked that in England the pip in fowls is called croup, and that he had no doubt that it had some connexion with diphtheria in the human subject. M. Delthill referred likewise in his paper to intestinal diphtheria, the existence of which was undoubted in the human subject, and of frequent occurrence in the calf.

VACCINATION AND THE DEWSBURY GUARDIANS.

THE difficulties which, for a long time past, have existed in the Dewsbury Union as to the administration of the Vaccination Acts, have by no means been removed by the recent action of the Local Government Board on the one hand and by that of the guardians on the other. Owing to the part taken by the guardians and their late vaccination officer in this matter, the Local Government Board a short time since issued an order specifying the conditions under which the vaccination officer was to perform his duties; but the Dewsbury guardians, finding this unpleasantly precise and strong in the direction of the fulfilment of the provisions of the statute, came to London and interviewed those who were then at the head of the Board, with the result that the central authority, after years of experience as to the real feeling of a number of these guardians as to vaccination, gave in, cancelled the order, and prepared a second one in its place. This substituted order has now been discussed by the guardians. It provides for the appointment of a single vaccination officer, who shall be paid a specified fee; it also requires the guardians to appoint a vaccination committee, which shall meet at least once a fortnight to receive, amongst other things, an account from the vaccination officer of those cases in which he has served notices calling upon parents and guardians to fulfil the law as to vaccination; and it proceeds to say that the committee "shall thereupon give directions to the vaccination officer, with respect to the cases so reported, as to the legal proceedings to be taken if the requirements of the notices are not fulfilled within the time therein mentioned." Now, governed, as any such order necessarily must be, by the Vaccination Acts themselves, it would appear that the only legal effect of this order would be to interpose an interval of delay in the action which the vaccination officer must take under the statute to enforce compliance with the law, for no order can apparently relieve this officer from the performance of the duty "to enforce the provisions of this Act" specified in the statute. The guardians evidently see this, and although, as one of their number pointed out, they had been told by an inspector that "the Local Government Board would not alter the laws," yet they are making a further stand. One guardian, by way of opposing the terms of the order, moved that nine vaccination officers should be appointed instead of the one officer named in the order; but the case was more boldly met by a declaration that the whole difficulty lay in the use of the word "shall" in the order, and the speaker hoped the guardians would resent this, for he declined to be made a tool of even the most respectable Government. Unfortunately for the argument, however, the Vaccination Acts are compulsory, and not permissive; and hence we do not see how, even if the Local Government Board wished it, they can alter the "shall" into the "may" which would enable the guardians to do as they liked, instead of being the instruments for carrying out a beneficial and salutary law. In the end, objection was taken to that part of the order which necessitated the giving of instructions to the vaccination officer as to legal proceedings, and it was decided to prepare a letter to the Local Government Board explaining the reasons

why an alteration in the order, in this respect, was needed. The real question which is raised by this Dewsbury case is whether the law as to vaccination is to be carried out or suspended at the whim of the local guardians. The chairman, in fact, explained that the object of the Dewsbury guardians "was to prevent prosecutions of poor and helpless persons who were strongly opposed to vaccination," or, in other words, of people who were ignorant of the value of the protection afforded to the community by the operation; and it is certain that if the guardians did not enforce the law against these "poor and helpless" ones, they would not enforce it against themselves. So also, if such an order as the Dewsbury guardians want could be obtained for their district, there would be no reason why it should not be made general, and in this way the law as to vaccination would soon be abrogated. This it is that a few people, such as some of the Dewsbury guardians, want; and it is precisely this that the country and Parliament, which has passed a law which is to protect the "helpless" children of ignorant and careless people against the wholesale slaughter which small-pox causes in an unvaccinated community, cannot grant, whether by means of an order or otherwise.

CHOLERA BY POST.

ITALY, so far as her medical hygienists represent her, has shaken off her belief in land quarantine and in fumigations as counteractives to cholera; but she is still of opinion, if official regulation means anything, that the malady can be conveyed by post. Poor as she is, financially speaking, she can yet afford to burden her Ministry of Public Works with a heavy outlay for the practice of postal disinfection. But the money loss is not the worst of it. The practice keeps up a pernicious impression among her people, tantamount as it is to an official admission that the cholera contagium can be transported from place to place by a letter or a newspaper, so deepening the conviction in the ignorant majority that the disease is pre-eminently contagious. If (the populace may well argue) the Government thinks itself bound to disinfect folds of paper merely on the remote suspicion that they have passed through cholera-stricken hands; if Government *employés* specially told off for such disinfections are under rigid orders to touch those paper packets only with the tongs, and to put them into chests, exhaling carbolic acid before laying a finger on them,—what must not the danger be of approaching or touching a cholera patient, or even a person who has come from a cholera district? To tell communes that fumigations are useless, even prejudicial, and not to be applied to the stranger arriving on their frontier, and at the same time to deliver their letters and newspapers only when reeking with carbolic acid, seems curiously inconsistent to the popular mind, and not very edifying as a sample of official logic. Yet this is precisely what the Italian Government has done by the circular issued from the Sanitary Office on August 15th, 1885, and at this very moment still in force. So true is the remark of Pettenkofer that the question of cholera prevention is less one of science than of common sense. "If these practices are rational," says a high sanitary authority in Italy, "why apply them only when fear of cholera is imminent, while either before or after that period the post continually brings in correspondence from places where the disease is endemic? Since 1869, with the opening of the Suez Canal, postal communication with India has been multiplied, and yet no relative augmentation of cholera in Europe has been the result. England, indeed, offers us a standing example of the uselessness of such disinfections, disregarding them as she does altogether, and maintaining constant postal communication with the most infected spots of Europe and Asia. Conclusive evidence of the groundlessness of the fear of infection from correspondence is seen in the fact that letter-sorters and the *employés* in public departments and newspaper offices, who are in constant receipt of postal communications, are as little subject to cholera as their neighbours. Postal disinfection, in short, should be discontinued, as tending to induce or keep up popular panic, as a burden on the treasury, and as equally irrational with land quarantine, sanitary cordons, and fumigations of the person."

COCAINE IN ANGINA PECTORIS.

PROF. LASCHKEWITCH has found good results from the internal administration of cocaine (in doses of one-half to one-third of a grain three or four times daily) in cases of angina. It does not cut short an attack, but diminishes its intensity, and after a few days' consecutive administration it gradually diminishes the force and duration of the seizures until they may wholly disappear (*Rev. de Méd.*, Aug., 1886). He details four cases; one was that of a man thirty-five years of age, the subject of aortic regurgitation and dilatation of the aorta. Anginal attacks occurred as frequently as eight times daily, and were of the characteristic kind. He was obliged to keep his bed, but the attacks also occurred during the night, preventing sleep. The disease had lasted two years, and had not been much benefited by oxygen inhalation. Half-grain doses of cocaine were prescribed, with the result that the attacks became less frequent and shorter, eventually disappearing. The patient died subsequently of an infectious disease. Another case was that of a man aged sixty-three, with mitral disease, aortic dilatation and general arterial sclerosis. Anginal attacks had occurred during the past six months on physical or mental exertion, and were only subdued by morphia. Here, again, cocaine acted admirably, the angina ceasing after three days' administration. In a third case the patient, aged fifty-eight, presented marked arterio-sclerosis; the angina disappeared after two days' administration of one-third of a grain four times a day. The fourth case, a man about forty years of age, was one of aortic regurgitation with marked dilatation of the aorta; and the administration of cocaine speedily cut short the anginal attacks, which had become severe and frequent. Prof. Laschkewitch says that the remedy produces slowing of the pulse, which gains in volume; at the same time the quantity of urine is increased. He thinks that by combining this treatment with that by inhalation of oxygen, which acts immediately in an attack, the anginal seizure may be arrested, and its reappearance prevented.

THE CIRCULATION IN KAKKE.

THE July number of the *Sei-i-kwai Medical Journal* (published at Tókyó) contains a study of the condition of the circulation in kakké or beri-beri, by Dr. Wallace Taylor, in continuation of a series of articles he is writing upon this affection. He remarks that the condition of the circulation is the most striking and important feature of kakké—one group of symptoms, which has received the name "shiyoshin," resembling an attack of angina and frequently terminating the case fatally. Dr. Taylor has taken the pains to obtain sphygmographic tracings of a large number of cases, which are reproduced with the article and well illustrate the degree to which the cardiac power may be affected. In all the tracings there are to be observed the characteristics of a very sudden and high upstroke of the ventricular systole, a precipitous descent from the apex of the percussion wave, and dicrotism. The first departure from the normal is to be seen in the first-named feature, pointing to cardiac excitement, which occurs in early stages and mild cases of the disease. Then there is diminished arterial tension from loss of vaso-motor tone, indicated by the rapid descent of the sphygmo-

graphic lever, readily observed in the character of the pulse as felt by the finger, and marked by coldness of extremities, with lividity as the case advances. It is pointed out that, in spite of the gravity of general symptoms, the prognosis is favourable so long as there is no indication of cardiac failure, and of the two factors in the circulation, loss of cardiac muscular power is less serious than loss of vaso-motor tone. This is the condition which is most likely to lead to "shiyoshin" above mentioned; and the explanation of the condition is to be found in the action of the *materies morbi* of kakké upon different portions of the cerebro-spinal nerves and sympathetic system.

THE INTRA-UTERINE GALVANO-CAUTERY.

DR. P. LANDOWSKI spoke at the recent Congress at Nancy in favour of the action of the electro-cautery in membranous dysmenorrhœa. He expressed his belief that though this condition is doubtless chiefly met with in women who suffer from cachexia or some general disease, still the general condition is very frequently the consequence rather than the cause of the uterine disorder. He mentioned two cases in which he had applied the galvano-cautery, the os being first dilated, and the time chosen being five or six days after the cessation of menstruation. In one of the two cases a complete cure resulted. In the other the pain accompanying menstruation was relieved, but a piece of membrane the size of a penny was expelled at each recurrence of the period. This was probably due to a portion of the intra-uterine wall having been insufficiently touched with the cautery. At the same congress M. Apostoli stated that he had employed the intra-uterine galvano-cautery in a large number of cases of chronic metritis and endo-metritis with very great success. He does not confine the patient to bed during the intervals between the applications, and improvement very quickly follows the first few cauterisations. The author compares this method with that of scraping the intra-uterine wall with a sharp spoon, and considers that it has the advantages over the latter of being capable of exact graduation, of being more easily localised, and of not being so instantaneous. The result of the cauterisations is to cause the formation of a new and healthy mucous membrane.

UNIFORMITY IN REPORTS OF WATER ANALYSIS.

IN a paper read at the recent meeting of the British Medical Association, Dr. Whitelegge called attention to the undoubted fact that the multiplicity of numerical and chemical standards adopted in reports of water analyses causes great inconvenience to those who have to compare and interpret such reports. One analyst will state most of his results as milligrammes per litre, but gives the chlorine and nitric acid in grains per gallon. Another will prefer to return his results in parts per hundred thousand, and, instead of nitric acid, will speak of "inorganic nitrogen," or "nitrates or nitrogen as nitrates and nitrites," or "previous sewage contamination." What is needed is not an act of uniformity with regard to chemical processes, but some plan by which results which are practically identical shall always be expressed in the same way—the model being rigid enough to allow direct comparison of corresponding details in different reports, while sufficiently elastic to comprehend the different analytical methods, and to allow the addition of further details when necessary. Much of this would be accomplished by agreement upon three points:—1. To adopt a fixed numerical standard upon which to state all quantitative results without exception. The greater simplicity of the decimal system and conformity with foreign usage recommend the million or hundred thousand basis; and the former seems, of the two, the more convenient, being a rounder number, giving results readily translatable as milligrammes per litre, and magnifying minute quantities which are apt to appear insignificant in the second or third decimal places. The 70,000 basis (grains per gallon) is scarcely retained, except in reference to chlorine and hardness. 2. To adopt fixed chemical expressions in place of the synonymous or convertible terms now in use, especially in regard to chlorine and "oxidised nitrogen." Chlorine is a better standard than sodic chloride, since the latter involves an assumption by no means universally correct. Oxidised nitrogen is a concise, accurate, and convenient equivalent of "nitrogen as nitrates and nitrites," into which it is easy to translate nitric acid, nitrates, and previous sewage contamination. It is a plain statement of fact, and involves no theory. 3. To regard the different processes for determining the organic matter as alternative and parallel means to the same end, of which it is rarely necessary to adopt more than one, and to group them together accordingly. We are thus in no way compelled to prefer any method, or to ignore any, in attempting to systematise reports. The organic matter in water being a complex and very variable mixture of known and unknown bodies, it is necessary to select some one or more element, factor, or derivative as a measure of them all. Each analytic process has a different index, and organic carbon and nitrogen cannot be directly measured against "albuminoid ammonia" or "total oxygen consumed," any more than a zymotic death-rate can be deduced from an infantile mortality-rate. This difficulty does not arise in the case of inorganic matters, which are for the most part returned in their true ascertained proportions, not representatively by an arbitrary index.

THE NATURE OF JAUNDICE.

FOLLOWING in the lines of M. Chauffard, Professor Kelsch, of Val de Grace, writes in support of the specific nature and infective origin of catarrhal jaundice (*Revue de Méd.*, Aug., 1886.) He confirms the clinical observations of M. Chauffard, especially as to the urinary excretion, but is unwilling to accept the doctrine that the condition is due to ptomaines formed in the intestinal tract, regarding an external agent as more probable. The observation of epidemics of jaundice in the army, of which he records instances, points to the conclusion that they are due to telluric conditions, and therein establishes a link between catarrhal jaundice and malignant jaundice. The latter is mostly admitted to be due to foul water-supply or bad drainage; and both varieties are frequently associated in epidemics. M. Kelsch, indeed, avers that the simple and malignant forms are one and the same affection, and therefore sums up his belief in the propositions that (1) sporadic or epidemic catarrhal icterus is a specific, infective disease; (2) that the infective agent is developed outside the organism; (3) that it is generated in marshes and in soil abounding in animal and vegetable matter; and (4) that owning thus a common origin with malaria and typhoid fever, the coincidence of epidemics of jaundice with ague and typhoid is explained.

LUNACY IN IRELAND.

THE thirty-fifth report on Lunatics in Ireland—which, by the way, is so summarised as to render it a task of considerable difficulty to ascertain the actual number of the insane officially known to the reporters—contains the following significant passage: "With reference to these admissions we cannot but think from personal observation or visits of inspection to asylums, and the opinions of resident physicians in them, that in the past year, much more than previously, acute attacks of insanity were caused by a want of nutritious

food, and at the same time by a continuous indulgence in RAW spirituous liquors of bad quality. The patients so affected, and physically of good frame, were recognisable from their pallid, emaciated features, extreme irritability, waywardness, and disposition to violence." This is a matter of much moment, and ought to be investigated. The reporters also speak of insanity feigned to obtain and secure the opportunity of self-destruction.

M. CHEVREUL.

OUR Paris Correspondent writes:—The programme of the fêtes in honour of M. Chevreul, an account of which was given in my letter of last week, is being punctually carried out. Yesterday at the meeting of the Academy of Sciences, which took place under the presidency of M. Blanchard of the Museum, M. Chevreul, on entering the hall, received the hearty congratulations of his fellow-members, who read numerous telegrams of a complimentary character. The President delivered an address on behalf of the Academy, congratulating M. Chevreul on having to count the days, weeks, and years of a new century, and expressing a hope that they might be numerous. M. Chevreul, in responding, cited as a proof that a man's reputation greatly depended upon the trial of time the examples of Newton and Liebnitz. "The latter said: 'Seek the demonstration first of causes.' Newton preferred the idea, much more prolific: 'Seek the cause of phenomena, and, when you have found it, inquire what is the cause of that cause.' There is a wide gulf between the two formulas. To my mind, Newton is greater than Leibnitz. Time has proved it."

DARENTH HOSPITAL.

AT a meeting of the Metropolitan Asylums Board held on Saturday last, a letter from the Local Government Board was read declining to sanction the erection of a permanent hospital at Darenth, and pointing out that a temporary hospital could be provided at a sum which only amounted to five years' interest on the larger sum which would be required for permanent building. The Board's letter has been referred to a committee, but much dissatisfaction was at the time expressed at its tenour. The Local Government Board are evidently feeling the difficulty of permitting large sums of money to be spent in the creation of hospitals constructed in the same manner as those which have been shown to be a fertile source of disease to the neighbourhood in which they are placed. Certainly there is need for an early determination of the question as to how small-pox hospitals should be built which can give all the necessary opportunity for isolating infectious persons, without in their own turn being sources of mischief.

ABSURDITIES OF THE RULE ABOUT DECORATIONS.

WHY in the names of common sense and social expediency should a subject of Her Britannic Majesty, who has been honoured by the sovereign of another state for services rendered to the cause of life and health, be denied the privilege of wearing the symbols of the honour conferred upon him, when the soldier, sailor, or consul similarly honoured for some deed of gallantry, or service of war, or politics, is permitted to wear his decorations? Nothing but carelessness or prejudice, surely, can account for the existence of so absurd a rule. If English practitioners of medicine are to be treated in this fashion, the matter had better be understood, and when the sovereign of a foreign State offers a decoration, it should be declined on the ground that, however acceptable in itself, it will be useless by reason of the narrow-minded jealousy that prevails at home. All the same, English physicians and surgeons will go on doing their utmost to save life and promote health, although the recognition of such services in other countries will be worthless in their own.

CONCUSSION.

A RAILWAY accident in which passengers are merely concussed may be the cause of a curious mixture of diseases. Concussion may be regarded as that form of shock which is independent of the conscious intervention of the individual concerned. Some of the passengers may suffer from symptoms that soon pass away; others will become the subjects of nervous diseases of long, if not permanent, duration. There can now be no doubt that organic, as well as functional affections, of the nervous system may arise as the outcome of an accident that causes concussion. The inflammation of the spinal cord that sometimes immediately follows concussion has a tendency to pass away; but this regressive quality is necessarily of slow kind, and may also be abolished in the presence of a syphilitic, gouty, or other pronounced diathesis.

DIRECT REPRESENTATION IN SCOTLAND.

DR. ROBERT SINCLAIR of Dundee has, we understand, entered the field as a candidate for the direct representation of the profession in Scotland in the Medical Council. This step has been taken at the instance of the Forfarshire Medical Association, of which Dr. Sinclair was secretary for several years. Dr. Sinclair claims to represent the practitioners as such independently of the interest of any teaching or examining body. A committee has been formed of medical men in Dundee and the neighbourhood, in the first instance, for the purpose of promoting his election. Dr. Greig is president and Drs. Stalker and Reid, joint secretaries.

HEAT DESTRUCTIVE TO THE COMMA BACILLUS.

AT a recent session of the Academy of Sciences in Amsterdam, Prof. Forster stated that he and Dr. van Geuns had found that the comma bacillus was destroyed by heating the substance containing it to 55° C. In their work "Les Bactéries," MM. Cornil and Babes state that the comma bacillus is destroyed by exposure to a temperature of 50° C. for a few days; also that a culture of comma bacilli can be sterilised by slowly heating it to 65° or rapidly to 75° C.

FOREIGN UNIVERSITY INTELLIGENCE.

Berlin.—Dr. Albert Guttstadt, who is known as an authority on medical statistics, has been appointed an Extra-ordinary Professor. Dr. Sell, who has hitherto given instruction in the chemistry of foods, and who is a member of the Imperial Sanitary Board, has been appointed to the newly established Professorship of Alimentary Chemistry.

Innsbruck.—Dr. Joseph Moeller, of the Vienna Forest Department, has been appointed to the Professorship of Pharmacology and Pharmacognosis.

Graz.—Though the Surgical Chair has been given to Professor Wölfler by the Government, his was not the name sent up *in primo loco* by the professorial body, this place of honour being reserved for Professor von Winiwater.

Prague (German University).—Dr. Richard Maly, of Graz, has been appointed to the Professorship of Chemistry.

Prague (Bohemia University).—Dr. B Edler von Jirus of Agram, has been appointed Professor of Pharmacology and Pharmacognosis.

Würzburg.—The Surgical Chair, vacant by the lamented death of Professor Maas, has been given to Professor Schönborn of Königsberg.

BOLOGNA celebrates this week the first centenary of its townsman Galvani's discovery of animal electricity. On the façade of his house, 29, Via Ugo Bassi, has been placed a tablet with the following inscription translated from the Latin of its author, Don Mignani: "On the 1st September, 1786, as the sun was setting, Luigi Galvani observed the first movements of the dead frogs suspended from this iron railing."

THE adulteration of bread and chocolate has gone to such lengths in Italy as to bring the sale of these articles under the special surveillance of the criminal authorities. Dr. Carlo Anfosso, in two elaborate treatises, has the merit of having called attention to the subject.

THE International Statistical Institute, which was to have met in Rome in September, has had to adjourn its meeting until next year, owing to the apprehension that the cholera, which has been spreading in Italy, may extend further, and possibly to Rome itself.

INTELLIGENCE comes from Vernoe to the effect that cholera has broken out at Aksu, in Central Asia, and that Kashgar is also threatened. In consequence of this, quarantine regulations have been established on the Russian frontier.

Pharmacology and Therapeutics.

DEEP INJECTIONS OF YELLOW OXIDE OF MERCURY IN SYPHILIS.

DR. SHABEK gives in the Proceedings of the Kieff Medical Society an account of some observations made in Professor Stukovenkoff's clinic on the employment of yellow oxide of mercury injections in the condylomatous stage of syphilis. The solution used was prepared by rubbing up sixteen grains of the oxide with twenty of gum arabic, and an ounce of water. The injections were made not hypodermically into the subcutaneous tissue, but, according to a plan recommended by Professor Smirnoff of Helsingfors, the needle, which was four or five centimetres in length, being plunged almost vertically into the gluteal muscles. In three cases five injections were given; in one case, four; in one, six; and in one case, ten injections were administered at intervals generally of a fortnight; a grain of the yellow oxide being introduced each time by means of two separate punctures on opposite sides of the middle line. In some cases, however, half a grain was injected weekly. The writer found these injections well borne by patients, only very slight local signs of irritation being induced, and in many cases none at all. In one case there was a hard swelling as large as a nut, but it was not painful, and soon passed away. The mercury, too, was always very quickly absorbed, being detected in the urine in four of the cases after the lapse of twenty-four hours from the first injection, and at the end of forty-eight hours in the other two cases. Dr. Shabek remarks that this method is inexpensive, simple, and efficacious, and will probably be found particularly useful in what in this country would be described as club, union, and dispensary practice.

ANTIFEBRINE.

Drs. Cahn and Hepp have been investigating the therapeutic properties of a chemical substance, which has long been known under the names of acetanelide and phenylacetamide, the formula of which is $C_6H_5NHC_2H_3O$, and which they propose to call *antifebrine*. It is a white crystalline powder, soluble in alcohol or wine, and in hot, but not in cold, water. They gave it in considerable doses to rabbits and dogs, and, finding it entirely free from deleterious effects, they administered it to twenty-four patients with fever, eight having typhoid, five erysipelas, four phthisis, two articular rheumatism, &c. The doses given were from four to fifteen grains, as much as thirty grains being given during the day. The dose required varied with the case. Generally speaking, it was found that it produced about as much effect as four times the same quantity of antipyrin. So far, the writers have never seen any case in which antifebrine failed to lower the temperature. The effect began to show itself in about an hour, attaining its maximum in four hours, and ceasing to produce any diminution in from three to ten hours more. A dose which was strong enough to reduce the temperature to normal usually kept it so for from six to eight hours. The fall of temperature was generally accompanied by a redness of the skin and increased perspiration. The subsequent rise was not accompanied by cold sweats, though sometimes the patients complained of feeling cold. The pulse diminished in frequency *pari passu* with the fall in temperature. No disturbance of the digestive organs was ever observed. Sometimes, indeed, the appetite returned whilst the temperature was low. Occasionally there was thirst and an increased excretion of urine. In some cases, too, there was a blueness of the face and extremities. In one case of acute rheumatism the pain in the joints and the fever disappeared rapidly after commencing antifebrine. The price of the drug is moderate, being under fifteen shillings a pound.

HYPODERMIC INJECTIONS OF CALOMEL IN SYPHILIS.

Professor Stukovenkoff reports very favourably in the "Zemskaya Meditsina" on the antisyphilitic treatment recommended by Professor Scarenzio. This consists of the hypodermic injection of calomel suspended in glycerine, or, better still, in a mucilage of gum-arabic. The localities chosen for the punctures are the gluteal regions. A grain and a half of calomel is injected on each side, making a total dose of three grains. This double injection is repeated at the end of two or three weeks, and that as a rule concludes the treatment, for it is rarely necessary to have recourse to a third dose. The author has practised these injections for a whole year, and is convinced that they never give rise to serious evil consequences. In two or three days after the injection a swelling appears at the seat of puncture, but the skin is not reddened, and it diminishes in three days and passes away in a fortnight, never becoming an abscess. The syphilitic symptoms rapidly vanish; gingivitis and salivation never occur. Comparing this method of treatment with that of inunction with mercurial ointment, Professor Stukovenkoff says that from three to nine grains of calomel injected in the course of from four to six weeks are equivalent to from thirty to forty inunctions of half a drachm of grey ointment. This plan has the advantages of simplicity, convenience, and of extreme cheapness. The mercury can be detected in the urine from two to four weeks after the commencement of the treatment, or somewhat later, and in smaller quantity than when other methods of mercurial treatment are employed. Before the injection is given, it is important to shake up the mixture well; also to see that it is quite white, as a greyish tinge indicates that the calomel is being partially reduced, and that the preparation is unfit for use.

SULPHATE OF SPARTEINE.

Hans Voigt, working in Nothnagel's clinic, has come to the following conclusions respecting the therapeutical action of sulphate of sparteine. In small doses the salt increases the efficiency of the cardiac contractions and raises the arterial pressure. The number of heart beats is always increased. These effects are observed within an hour of the administration of the drug, and continue for twenty-four hours. The author recommends the suspension of the administration of the drug for some days, but it may be given for a week without risk. The remedy does not always regulate the rhythm of the heart beats. Its action on the respiration is variable. Diuresis appears to take place in proportion to the improvement of the cardiac action. A beneficial sedative action is often observed. Headache, vertigo, malaise, and other objectionable symptoms were but rarely met with as the result of the administration of small doses. The dose employed has been from one to four milligrammes. It will be remembered that in Sée's hands much larger doses (five to twenty centigrammes) were tolerated without cumulative or other objectionable effects

NAPHTHALIN AS AN ANTHELMINTIC.

Dr. Coriander of Samarkand recommends naphthalin as a valuable and economical remedy, especially in country and military practice, for worms, both tænia and ascarides. He gives children of from one to three years of age 2 or 3 grains twice a day. In the case of adults he gives from 20 to 80 grains a day in powder with sugar.

JAMES G. WAKLEY, M.D.

ON the morning of Monday last, the 30th ultimo, Dr. James G. Wakley, who for the last five-and-twenty years has had editorial control and management of this Journal, died at his residence, Heathlands Park, Longcross, near Chertsey. About three years since, a small ulcer, induced by the irritation of a jagged tooth, appeared on the left side of the tongue. This ulcer in the course of time assumed an epitheliomatous character, and spreading towards the pharynx ultimately caused death by asphyxia. But, in spite of considerable suffering, Dr. Wakley continued to perform his editorial labours with his accustomed regularity and energy till a few months ago. Even when he was no longer able to bear a railway journey to town his interest in his life-work did not abate. Within two or three days of his death some proofs of articles which appeared in our last issue were submitted to his judgment and discretion. Such manly courage is at least worthy of praise. He knew he was the victim of a fatal malady, but, like a wise and brave man, he strove as far as his physical strength would allow to do the work of this life, while at the same time he humbly sought to prepare himself for the next.

Dr. Wakley was born in Thistle-grove, Brompton, in December, 1825, and was the youngest son of the late Thomas Wakley, M.P., the well-known coroner and politician, and founder of this Journal. His general education was conducted first at a private school at Hanwell, and afterwards at University College School, London; and his professional training was obtained at University College. He became a Member of the Royal College of Surgeons of England in 1849, and graduated Doctor of Medicine at King's College, Aberdeen, in 1852. He never engaged in medical practice, but at about thirty years of age began under his father's guidance a journalistic career. He was soon entrusted with a large share of editorial responsibility, and about the year 1859, when his father's health began to decline, he became actual, though not nominal, editor. Indeed, a loyal and jealous regard for his father's name and fame made him shrink from assuming the title of editor as long as his father lived. It was not till Mr. Wakley's death in 1862 that he finally took this designation, becoming at the same time half-proprietor of the Journal with his eldest brother, Mr. Thomas H. Wakley, F.R.C.S., who still survives him. It was no light or easy task to follow such an editor as the late Thomas Wakley, but events soon showed that the son was not unworthy to wear the father's mantle. Concrete and tangible proofs of his success as an editor and exponent of professional opinion and aspiration were speedily forthcoming. He not only maintained but extended the reputation which THE LANCET had acquired under its founder's direction for earnestness of purpose, strict integrity, and unselfish zeal for the public good and for the welfare of the best and permanent interests of the medical profession. The last letter which the late Mr. Wakley wrote to his son contained these approving and encouraging words:—

"Your exertions on behalf of the Journal are above all praise. They could not have been greater or more successful. The gratitude of the whole family is your due, and it will be freely bestowed. Your knowledge of the fact that your labours are so highly appreciated will, I trust, be a lasting source of satisfaction to you. ..... The Journal, I think—thanks to your late great efforts,—was never more prosperous than now: the three numbers which you have sent to me are admirable."

This high opinion was subsequently fully justified by the continued and growing prosperity of THE LANCET, and was endorsed in a significant and agreeable way in an address, which was presented only last week to Dr. Wakley by the present and past members of his editorial staff.

To this address, as the effort to speak produced much suffering, Dr. Wakley wrote the following touching reply, which may be regarded as the latest act of his editorial life:

"Heathlands Park, Longcross, Chertsey.
"August 30, 1886.

"MY DEAR FRIENDS,—On Thursday last, August 26th, Dr. Glover and Dr. Coupland paid me a visit for the purpose of presenting me, in your names, with a very handsome address on vellum, and a number of letters from individual Members of my Staff. No words could express my feelings of gratitude to you for having in such touching terms conveyed your kind and generous sentiments. It is most comforting, in what I feel and know to be my last illness, to learn that my life-long work for THE LANCET has merited and gained your esteem. Thanking you for your tender sympathy and regard, I am yours affectionately,

"JAMES WAKLEY.

"To the Members of the Staff of THE LANCET."

Though from his position Dr. Wakley necessarily played an important part in all matters concerning Medicine in its relations to the State, the public, and the profession, his life was, perhaps, less eventful than that of many lesser personages. It had a twofold aspect. In one he was absorbed in editorial labours; in the other he delighted in such pursuits and pastimes as a rural residence at once invites and supplies.

The editorial life of Dr. Wakley was one of peculiar devotion. He was seldom seen in London save in his editorial room, or on the way between Bedford-street and the Waterloo Station. Few men have met him in society during the quarter of a century that he has laboured so hard. Even his most intimate friends have never been able to detain him in town. The coldest winter night could not deter him from the long railway journey, and the bleak drive and ride across Chobham Common to his lonely but much-loved home at Longcross. This was largely due to his pure love of the country. He was never more at home than in his saddle, or with his gun, or among his dogs, save when he was in his editorial chair receiving one member of his staff after another, or half-a-dozen at a time, with a kind word for each, even if it covered a mild rebuke or a gentle disapproval of something written or proposed. And in this chair he was to be found with great regularity. Other people might take long and distant holidays, but they had no charm for him. He was essentially a journalist, and to make THE LANCET effective he spared no pains night or day, summer or winter. His first care was to make this journal the exponent of the views, scientific or professional, of medical practitioners in every

part of the kingdom and of the empire. Such views might not always be perfect in form or in demonstration, but so long as they came out of honest observation and practical experience, they commended themselves to Dr. Wakley, and a place was found for them in THE LANCET, and for such criticism as they seemed to demand. In his estimation there was no calling like that of Medicine, and no life more useful or honourable than that of the medical man. The scene of the practitioner's labours might be but a village or a thinly populated country, but there was scope enough in such a sphere for every medical virtue. Wherever disease was to be found, and a worthy medical foeman was to be seen in active conflict with it, there was material for the admiration and vindication of Dr. Wakley. For such a practitioner to be underrated or underpaid, for him to be lightly esteemed either by the patients to whom he ministered or the Medical Bodies who had certified his competency to practise, was an injustice which he could not bear. But it was not merely the hard-worked practitioner whose labours and whose hardships excited the interest of Dr. Wakley. He had a keen eye for the men of promise and investigation in the profession. Such men had not to wait for accomplished fame before they attracted his notice. He was quick to see them, and proud to bring them into the service of the Journal which he loved with a filial love. Many a medical man now comfortably removed from professional anxiety, and enjoying the fruits of scientific and literary labour in medicine, will be ready to admit that Dr. Wakley was one of his earliest and kindest friends. One of the great tests of a good editor, indeed, is this eye for men of light and leading, and next to that the faculty of attracting them to himself and to his journal before they become hopelessly absorbed in the distractions of practice and in the pursuit of fame. Judged by these tests Dr. Wakley was an editor alike by inheritance and by nature.

But we should form a very inadequate estimate of the late Editor of THE LANCET if we thought of him as a mere medical man, who could not see anything but the medical profession and its interests. On the contrary, he held that what was best for the public was best for the profession. The whole history of THE LANCET, indeed, shows a far wider view of the uses and functions of a medical paper. Civilisation teems with questions having medical bearings, and which cannot be settled without the assistance of medical science. We need not go further back than the time of Dr. Wakley's editorship to find such questions, or to estimate the uses of a medical paper in settling them. Let us enumerate but a few of them: The duties of the State to the poor, especially the sick poor; to those affected with infectious disease; to the insane: the duty of the State to those needing protection from disease; from employments involving disease; from schools and educational systems of an unhealthy or unnatural kind. Dr. Wakley's interest in such questions was acute, and it never flagged. Those members of his Staff who can recall the energy with which he directed the inquiry into the state of the sick in workhouses, carried out by Anstie, Hart, and others, and the attention with which he followed the disclosure of every miserable defect of nursing, of bedding, of gas, of cubic space, and of food, and who can compare it with the interest with which he regarded the recent question of School-pressure, will best judge how sustained was his sympathy with all classes who could not help themselves. No class escaped his care or his criticism. He was as ready to investigate complaints against a Public School as those against a Board School; the defects of a palace used by our Royal Family as those of a workhouse bed too short for the projecting limbs of Timothy Daly. And so it came to pass that under his care, as under that of his respected father, a medical journal had no slight importance for the public, who looked to it for guidance in matters of health and happiness. Nor was his interest solely confined to human beings. He was a great lover of animals. Those who remember the cattle plague will recall his great interest in the investigations of Murchison, Gamgee, and others as to its nature and as to the best ways of dealing with such a national calamity. His love of animals led him, on the one hand, to be a stern advocate of carefully regulated vivisection, which has done so much to elucidate their diseases as well as those of man; and, on the other, to disapprove all careless or heartless treatment of the lower animals. Even those forms of sport which involved a very unequal contest between man and the lower animals were always denounced by him in his editorial and personal capacity. His views on the subject of medical legislation are well known, and it is no secret that he was deeply dissatisfied with the recent Act. He was not under the peasant delusion, which seems to possess some, that the mere concession of direct representation will do everything. His great wish and object was to have procured a one-portal system and a reduction of the rivalry and competition of Examining Bodies. And it was not his fault that less adequate legislation was accepted.

Dr. Wakley's characteristics as an editor were very simple. He made no pretensions to great learning or a deep acquaintance with science. But he had an ample store of common sense, and a power of very quickly and surely gauging professional opinion. When he once formed an opinion he stuck to it with tenacity and courage. He was singularly free from personal or malicious feeling, though strongly tempted thereto occasionally in the conflicts raised by the views and criticisms of the Journal for which he was responsible.

We have spoken of Dr. Wakley's delights in a country life and in country pursuits; but these delights were by no means purely selfish. In the country, too, he enjoyed the luxury of doing good. Many of his acts of benevolence and philanthropy were too constant and far-reaching not to be on men's tongues; but not even his most intimate friends were permitted to see or know of all his generous deeds. The lives of hundreds of poor people in the neighbourhood where he resided have been brightened and their homes made happier by his kindly and discriminating help; and in his death he has not been unmindful of the difficulties and struggles and hardships which might otherwise be in store for many of those whom he aided and cheered during his life.

During the long months in which he calmly and resignedly awaited the approach of death, Dr. Wakley derived much

peace and happiness from the consolations of religion, and from the ministrations of his friend the Rev. Thomas Stirling Coles, M.A., of Chobham.

Some time before his death he made a special request that the following confession of faith should be introduced into any notice of his life which might appear in the pages of THE LANCET:—"Feeling my deep responsibility to God for the position in which, in His providence, He has placed me, I desire to testify to the comfort derived during my sickness from a lively faith in our Lord Jesus Christ, and that I die in the sure hope of a glorious resurrection."

Dr. Wakley especially wished that it should be known that for a long series of years he was materially aided in anxious editorial work by Mr. Tweedy, by Dr. J. A. Marston, and by Dr. J. G. Glover. With these gentlemen he had for many years been very intimate, entertaining great regard and esteem for them, and having great reliance in the soundness and fairness of their judgment, their scientific and literary ability, and the integrity of their character. He was also anxious that tribute should be borne to the work done by Dr. A. H. Hassall, when THE LANCET exposed the adulteration of the food of the people, and to the long and faithful services of Mr. H. A. Beckett, the present Sub-editor of the Journal. For the last three years the late Dr. Wakley was assisted in his editorial duties by his nephew, Mr. Thomas Wakley, jun.

It would be an omission here not to notice the medical care and kindness which Dr. Wakley met with from his many professional friends during his long illness. The personal attention he received at home from Mr. Barford, of Wokingham, sometimes in the middle of the night, extended over a period of two years. Latterly Mr. Braybrook, a medical student, resided constantly in the house as a companion. And Dr. Angel Money and Mr. Pepper for several months past have gone down on alternate nights to Longcross, quite regardless of their own convenience. Such ministrations in sickness are the luxury of a medical man.

The interment will take place at Chobham Parish Church this day (Saturday), at 3 P.M.

HEALTH OF THE ARMY.

No. III.

DURING the year 1884 there were 66,882 recruits inspected, being 7448 more than in the preceding year; and the number rejected, including 254 found unfit within three months of enlistment, was 27,888, or 417 per 1000. But from this should be deducted 2289 under height, and 717 apparent age not in accordance with general order—both clearly military causes of rejection. Such recruits ought not to have been brought forward for medical inspection, but have been refused by the recruiting parties; this would reduce the ratio of rejections to 372 per 1000. There is a marked difference in the results of the primary examinations conducted by the medical officers and civil medical practitioners, the proportion rejected by the former being 415 per 1000, and by the latter only 177; but to this must be added 226 found unfit on secondary inspection, making a total of 403 per 1000 of the civilian examination. The proportion of recruits furnished by each country was—England and Wales, 753: Ireland, 139; Scotland 97; and the Colonies, 11 per 1000. The highest ratio of rejections was of the Scotch, and the lowest of the colonial recruits.

The proportion rejected in the different arms of the service ranged between 427 per 1000 for infantry regiments and 350 for the Royal Engineers. Nearly one-fourth of all the rejections was for "under chest measurement," the cause assigned for 102 per 1000 examined; "under weight" was the cause of 60 per 1000, and defective vision of 38 per 1000. One man was rejected for "over height," but no information is given either as to his height or as to the regulation maximum height which he exceeded.

Compared with the results for 1883, the returns show a decrease in the number of recruits under eighteen years of age and in those from nineteen to twenty-two, but a considerable increase in those from eighteen to nineteen—a result which is, we think, to be regretted. The table of the heights shows a decrease in the proportion under 5 ft. 5 in. The chest measurements show a falling off in the numbers above 33 inches and a considerable increase in the proportion between 31 and 33 inches—a result most probably arising from the reduced ages of the recruits. As regards occupation, there has been an increase in the proportion of labourers, servants, husbandmen, &c., and of shopmen and clerks, and a reduction in manufacturing artisans and mechanics. The proportion of well-educated recruits shows a marked increase, while that of men unable to read has fallen to 113 per 1000. There is obviously, however, still a good deal of work to be done by the army schoolmasters. Of the recruits found fit for service, 917 per 1000 bore marks of vaccination and 28 of small-pox, while 53 per 1000 had no satisfactory marks; 32,416 were revaccinated and 914 primarily vaccinated. The beneficial effects of this system of vaccination are shown by the fact that in an aggregate force of 167,686 men scattered over the world, only 121 cases of small-pox and 9 deaths occurred during the year, or about 72 cases and 5·37 deaths in 100,000 men.

In the Appendix to the volume, although the events did not occur in the year under review, there is a report on the medical and surgical transactions of the Suakim expeditionary force, by Deputy Surgeon-General Oliver Barnett, who was principal medical officer. The period included was from March 1st to May 14th, 1885, or seventy-five days. The average strength of non-commissioned officers and men is stated at 7235. The admissions into hospital were 2146; the deaths, including under that term also the missing, 104, which would give an *annual* ratio of 1347 cases and 65·29 deaths per 1000. Of the deaths, 47 were in action and there were 40 returned as missing, the two making an *annual* ratio of 54·61 deaths under this class. The only other important cause of death was enteric fever. There were 88 cases of this disease, of which 11 terminated fatally, being respectively in the *annual* ratio of 55·2 and 6·90 per 1000. Except the death-rate, these are all higher than in the Nile expeditionary force in the preceding year. There are some interesting details given respecting the medical arrangements of the force and the nature of the wounds received in the three principal actions in which the force was engaged. We must content ourselves with noticing only two of the remarks on the general arrangements. The Principal Medical Officer states that, the field hospitals "being non-dieted, field rations were used, cooked according to requirements, and supplemented with medical comforts, such as beef-tea, arrowroot, milk, cocoa, port wine, and anything else the medical officer considered it necessary to obtain from the commissariat stores, which in this campaign were most liberally supplied for the use of the sick. The National Aid Society's stores were therefore superfluous, and in no instance were they required for the use of the sick." The other remark was made by the Surgeon-Major of the Coldstream Guards in medical charge of No. 4 field hospital: "No spirituous liquors have been used during the campaign, and I am of opinion their absence has largely contributed to the efficiency of the troops during the arduous duties performed by them." The report states that 5 officers were killed and 1 missing, 5 were wounded and 1 invalided, but there is no information as to the numbers among whom these casualties occurred. This opinion as to the benefit arising from the absence of the means of intemperance is corroborated by Deputy Surgeon-General Faught in his report of "Medical Transactions with the Bechuanaland Field Force, South Africa," which appears to have enjoyed remarkably.

good health, but no details are given as to the amount of sickness and mortality. Mr. Faught remarks that, "whatever may be said to the contrary, it was the absence of abuse of drink and—thanks to the G.O.C.—the impossibility of procuring it, especially in the months of March, April, and May, when fever exists, if it does not prevail, and could prove fatal in six days, that caused no aggravation of the cases that existed, and may have caused the low rate of mortality when enteric lesions existed; and I hardly think there is an officer or man in the force who is not now convinced that the great health of the force is mainly attributable to this cause—enforced moderation." There is also a report of the field hospital (base) for followers sent from India to the Soudan, by Surgeon Hindley of the Indian Medical Service. These were about 6500 in number. In the three months of their service in Egypt they appear to have lost 22 men, or in the *annual* ratio of 13·54. The most prevalent diseases were dysentery and ague, and the most fatal dysentery. Some tabular information is given as to the diseases most prevalent and fatal among natives of India, Arabs, and Europeans respectively, but unfortunately the relative numbers serving are not stated. There appears to be considerable need of an improved organisation of the corps, with a view to increase its efficiency. In connexion with the campaign of 1885 there is also an interesting report by Brigade Surgeon Gribbon on the hospital ship *Ganges*, giving a detailed account of the arrangements made to fit her for this special service, and of the work performed during the seven months she was so employed, with some suggestions as to the construction and equipment of hospital ships.

The subject of huts, hut hospitals, and tents has received a good deal of attention. Professor Longmore has furnished a report on the "Competitive Exhibition of Movable Hut-hospitals at Antwerp in September 1885, together with a descriptive account of the pattern to which the principal prize was awarded." The first prize was awarded to a hut designed by Captain Doecker of the Danish Army. Professor Longmore has given a brief but clear account of the special construction of these hospitals and their advantages for ambulance purposes. There is also in the Appendix a "Description of Huts for Troops at Suakim," with drawings showing their construction and the accommodation they afford. The merits claimed for them are: simplicity of construction, good arrangement from a medical point of view, and economy. "Experience in India and Egypt led to the conclusion that the roof should be constructed of such material and thickness as to exclude the heat of the sun's rays, that the hut should be provided with verandahs, and that it should be capable of the freest ventilation; in brief, that the troops should, as it were, live in the open air under the shade of a thick cover." To effect these objects the roof is constructed of cork covered with waterproof Willesden paper, and with metal cowls along its ridge for ventilation. The ceiling is of inch boarding, and the ward or barrack space is supplied with permeable walls of matting set in frames and removable at will. The air above the ceiling communicates with the outside air at the ends and sides. There is an outside verandah, the walls of which are to be provided locally with bamboo chicks or matting, to roll up, so as when down to exclude the sun, or when up to allow of any breeze passing into the hut. The doorways are provided with chicks of permeable matting. The hospital huts are intended to accommodate twelve beds, with a space of 850 cubic feet for each, and the floors are raised eighteen inches above the ground to admit of a free circulation of air underneath. The huts are placed with the ends east and west, and the sides north and south. There is a floored verandah on the north side of each hut, sufficiently wide to enable the invalids to be moved out in their beds if necessary. Lavatories and earth-closets are provided at the south-east corner, under the verandah. These huts appear remarkably well calculated for the purpose for which they are intended, and a great improvement upon anything yet carried into effect. We regret that no information is given as to the expense of construction. Surgeon-Major Fleming, in some "Notes on Equipment, &c., taken during active service in the neighbourhood of Suakim," discusses the question of tents for field service. As the result of his experience in the hot season during the last Afghan war, he has come to the conclusion that the bell tent in use in the British army is the very worst as regards healthfulness, and that "the best form of tent and the most suitable for field service in any climate is the ridge-pole double-fly tent, of a shape similar to those known as the Cabul pattern tents, and with a few modifications used by sportsmen, emigrants, &c., throughout the world." A drawing of this tent is given in the report. Dr. Fleming has also made some suggestions for the improvement of the equipment, which deserve consideration.

Besides those we have already noticed, there are some other papers of interest in the Appendix. Of these, we would specially indicate Notes on Cases of Hydrophobia in India and Statistical Notes on Suicide in the Army. We have the usual contribution by the Assistant-Professor of Military Surgery of the operations performed at Netley during the year, with short abstracts of the more important cases; but we have still to regret the absence of any communication by Professor de Chaumont on the progress of hygiene, or any account of the work done during the year in the sanitary laboratory at Netley; nor do we find any contribution from the medical branch of our great invaliding hospital. In spite of these omissions, however, we look upon the volume as containing much valuable matter, and reflecting great credit upon the Department.

PARTIAL EXCISION OF THE LUNG AND NEPHRECTOMY: RECOVERY.

IN the *Bulletins et Mémoires de la Société de Chirurgie de Paris* (tome xii., No. 6, July, 1886), Dr. Demons of Bordeaux publishes the very remarkable history of a man who recovered after removal of a portion of the left lung and of the corresponding kidney.

In the night of Aug. 30th-31st, 1885, P. C——, a robust labourer, aged forty-nine, was conveyed to the Hôpital Saint André with two wounds, which had been inflicted with a knife during a quarrel. One of the wounds, ten centimetres long and comparatively superficial, was on a level with the ensiform cartilage, and healed quickly; the other wound was on the left side of the thorax, between the ninth and tenth ribs, parallel with the intercostal space. It was 4 centimetres in length, its posterior extremity 14 centimetres from the spinous processes, while anteriorly it reached to within 27 centimetres of the ensiform cartilage. On this wound was visible a rosy, smooth, soft tumour, with the appearance of lung. There was no hæmorrhage, no hæmoptysis, and no subcutaneous emphysema. On percussion, the resonance of the left side of the lung was slightly augmented; on auscultation, the respiratory murmur was rather weak, and a slight metallic tinkling was audible occasionally. The patient was oppressed, and troubled with a frequent dry cough. The assistant on duty made no attempt to reduce the hernia of the lung, and merely applied an antiseptic dressing. The following morning the tumour was of deeper red colour and firmer consistence. Slight pressure neither produced crepitation nor decreased volume. The urine was deeply tinged with blood, inducing the belief that the knife, after penetrating the thorax, had passed into the abdomen and wounded the left kidney.

Sept. 1st.—Nausea; severe pain in the left flank. Temperature: morning, 38·8°; evening, 39·5°; pulse 120.—2nd: Very frequent bilious vomiting. Pain extending over the tympanitic abdomen; urine bloody. Ice internally and externally; opiate draught.—3rd: Slight dulness at base of left chest; abdomen very distended and painful.—4th: Pain and swelling localised in the left flank. Copious evacuation and marked relief, after a purgative enema. Temperature 38·9°; pulse 108.—5th, 6th, and 7th: Pain and doughiness more and more localised in the left flank. The patient is easier, but the protruded lung has acquired a greyish tinge, and the surrounding integuments are red and swollen.

Resection of the protruded piece of lung.—By means of the écraseur the protruded piece of lung was excised on September 8th. Although the instrument was worked slowly during half an hour, some dark blood exuded, and required the thermo-cautery for its arrest. No anæsthetic was administered, and the patient did not suffer during the operation. Listerian dressing. No hæmoptysis during the whole progress of the case.—9th: Œdema of the scrotum, chiefly on the left side.—10th: The inflammation which existed around the wound at the time of operation is more intense; slight œdema. Blackish and fetid pus evacuated through an incision of four centimetres; drainage.—11th: On withdrawing the drainage-tube, which was blocked, a con-

siderable quantity of sero-purulent fluid escaped. On the following days the dressings were soiled by a quantity of ill-conditioned pus, which issued with difficulty during cough; this had increased for some days, and was followed by mucous expectoration.—13th, 14th, and 15th: Fever intensified; temperature 39·6°; pulse 116. The patient does not micturate involuntarily, but careful dressing and observation strengthen the conviction that the pus which escapes from the thoracic wound emits urinous smell. Some of the discharge collected with a sponge was analysed by M. Dannery, chief pharmacien to the hospital, and found to consist of urine mixed with pus, with 30 grammes of urea to the litre; whereas the urine passed per penem (only 450 grammes in the twenty-four hours) contained 18 grammes of urea to the litre.

From Sept. 15th to the 25th, the local condition did not vary. Small abscesses formed around the thoracic wound, and the left hypochondrium continued swollen and painful. The temperature oscillated between 37·8° and 39·6°. On auscultation, some bronchitic râles were audible on both sides. At the left base there was a slight diminution of respiratory movement; no souffle; limited dulness in the same spot. The patient was losing flesh and strength.

Nephrectomy was performed on Sept. 26th under chloroform, with antiseptic precautions. A vertical incision fifteen centimetres in length was made at a distance of seven centimetres from the spinous processes, between the eleventh rib and the iliac crest. On incising the aponeurosis covering the quadratus lumborum, a large quantity (from 700 to 800 grammes at least) of fetid, greenish, thick pus escaped. When this flow, aided by pressure on the abdominal wall, had ceased, the abscess cavity was carefully cleansed. The kidney was then visible, denuded in great part of its fatty covering. From fifteen to twenty minutes were occupied in enucleating the upper part of the kidney, and the cortical substance was somewhat torn during the proceeding. Just when the kidney was being drawn upon to expose the pedicle fully, abundant hæmorrhage occurred. It was evident that one of the vessels in the pedicle had given way under traction. Hæmorrhage was arrested with two pairs of long forceps, and after dividing the pedicle close to the kidney, it was tied in two sutures with strong catgut and a Cooper's needle. For greater security a distal ligature included the whole pedicle. Some smaller vessels were tied, and the wound thoroughly cleansed, even into its smallest recesses. It was closed with four deep silver sutures and eight superficial silken ones. A drainage-tube as thick as the little finger was passed upwards to the bottom of the wound, and a similar one downwards. The edges of the thoracic wound were pared and united by three silver sutures.

Marked relief of all the symptoms followed the operation. Just before it the temperature was 39·4°, and it fell to 37·8° within forty-eight hours. The urine was neither bloody nor purulent, but became black in consequence of the absorption of carbolic acid, for which sublimate dressing was substituted the fifth day. The day after the operation the quantity of urine voided was 800 grammes, containing 8 grammes of urea; these numbers fell to 700 and zero respectively on the fourth day, and then gradually rose; so that on the tenth day 1200 grammes of urine were passed, with 18 of urea, and these figures reached 2200 and 42 on the seventeenth day. The wound healed by the first intention, except at the drainage-tubes, through which a considerable quantity of pus continued to flow. The tubes were shortened and finer ones substituted, but they were not wholly withdrawn until the expiration of two months; ten days before that date a parcel of sphacelated cellular tissue issued spontaneously from the upper part of the wound. It had been the cause of the persistent suppuration, which from that time rapidly lessened. The patient progressed favourably, and when he left the hospital, Dec. 21st, the urine was clear, amber-coloured, specific gravity 1022, without albumen; quantity in twenty-four hours 1920 grammes, with 10 grammes of urea. The patient resumed work and was seen in perfect health on May 20th, eight months within a week from the operation.

The piece of lung removed was of triangular shape and flattened. It measured 8 centimetres in breadth and 8½ in length. The breadth of the divided pedicle was 4 centimetres. The extirpated kidney was congested and 12 centimetres long. Its surface, in the upper half, presented several lacerations produced by the fingers during the operation. Possibly one of these wounds was inflicted by the knife at the time of the accident, but it is more probable that the kidney having been detached on a level with its inner margin, the wound which gave exit to urine was situated in the pelvis, or in the upper part of the ureter, and was included in the ligature of the pedicle.

THE BELFAST RIOTS.

THE following is a synopsis of the Report just presented by Mr. Foy, F.R.C.S.I. (visiting surgeon to the Whitworth Hospital, Dublin), the surgical commissioner sent down by the Irish Loyal and Patriotic Union to inquire into the nature of the injuries received in connexion with the late riots in Belfast.

It is only due to this gentleman to state that, as he says, this record is a purely surgical one, and as such, without tincture of politics, it is placed before the public. He bases his report on personal examination, supplemented by a large range of inquiries, and we propose to lay before our readers some of the principal points of interest in this document. The wounds were of two classes—gunshot and contused wounds,—these latter inflicted by stones, bâtons, and in only one instance that Mr. Foy could ascertain by the use of an iron nut. The gunshot injuries were of two kinds, those caused by bullets either from rifles or revolvers, and by buckshot. The bullet wounds were of the usual kind, and in the majority of cases ended fatally. The bullets were of the "regulation" size. The revolver wounds, the commissioner states, were, comparatively speaking, few in number, and as a rule were not fatal. Buckshot was very largely used, and in persons wounded at a considerable distance the shot barely entered the flesh, while in exposed parts and at near distances it was equally as dangerous as a rifle bullet. The greater number of the fatal injuries were inflicted on the head and chest. These injuries resulted in many instances from buckshot wounds, the pellets finding an entrance into the brain by the eye, or when fired at very close distances possessing sufficient momentum to penetrate the bony wall. Mr. Foy gives several instances of this penetration. It is curious that the majority of the injured were not in crowds, but were alone at the time they received their wounds, and this is markedly the case in those who received fatal injuries, and of this fact the commissioner gives ample evidence. The remaining class of injuries consists chiefly of bruises, mostly inflicted on the head, but occasionally on the legs, arms, and back. It is a very curious fact, as stated by Mr. Foy, that there was great freedom from broken bones, from rupture of bloodvessels, as well as from injury to the nervous system. The more serious bruises, especially those upon the head, and the few that were associated with fracture of the skull, were the result of bâton wounds. The knife was but little used. Mr. Foy gives the total of the number treated in connexion with the riots as 582, while the number of deaths may be taken, he thinks, at thirty-four. There were 146 serious gunshot wounds. Mr. Foy gives details of many cases, and in each of them to which distinct reference is made, special individual reports have been prepared, together with diagrams, which fully explain the exact nature and position of the wounds. The first gives instances of immediate death resulting from the infliction of wounds, one of the most painful of which was that of a woman, the mother of several little children, who was *enceinte*. She was shot through the skull. Mr. Foy gives examples of deaths from buckshot wounds, of cases where the bullets have remained embedded in the body, of cases remarkable for the narrow escapes the injured had, and of cases showing evidence of the slight power of penetration of buckshot pellets when fired through clothing. From cuts inflicted by sharp instruments the riots were particularly free. He has only been able to obtain evidence of twelve such. Bruises in these riots may be considered in two classes—those inflicted by missiles thrown, and those resulting from actual personal contest. Among the former the police were the principal sufferers. The commissioner thinks that from examination of the wounded, and from the amount of damage done by bullets on the bodies of those who died, there can be but one inference drawn—viz., that the firing was at close quarters. When death has been occasioned by bullets, the injury done was such as could only result from great force. In the case of pellets, the fact that the bones of the skull, and the whole depth of the body in some instances,

have been penetrated by a pellet shows how close must have been the assailants to the victim. Our impression is that Mr. Foy under-estimates the number of those injured in the riots, and since his report has been published we observe that the Chief Secretary for Ireland, in reply to a member of the House of Commons who asked a question in reference to the injuries received by the police, stated that a head-constable had been killed and that five officers and thirty-six members of the constabulary had been seriously injured. In all, he said that 332 members of the force of all ranks were more or less injured, although in many cases the injuries were not serious. Further, there is an impression in Belfast that as the result of what has been styled the "Springfield fight," where several of the antagonists were armed with rifles, and which lasted a whole night, a number of people were killed and have been secretly buried, no record having been kept of them. No doubt at the forthcoming Commission a great deal of information bearing on all these points will be disclosed.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Berkshire Combined Sanitary Districts.—The mortality statistics for the several urban and rural districts combined in the area for which Dr. Woodforde acts as medical officer of health show that during 1885 the highest general death-rate—namely, one of 20·0 per 1000—was experienced in the Cookham rural district; and the lowest—namely, 14·2—in the Windsor rural district. That for the entire combination reached 16·5 per 1000. The most important mortalities from infectious diseases were: in the Hungerford rural district, 9 deaths from diphtheria, besides 6 from croup; 8 from diphtheria in the Bradfield rural district; and 6 from the same disease in the Windsor rural district. In many instances no connexion was traced between outbreaks occurring almost simultaneously, and although in some cases the attacks occurred under bad sanitary conditions and in low-lying damp localities, yet nothing was ascertained which tends to clear up any of the obscure points connected with the etiology of this disease. Occasion has evidently been taken to secure a number of improvements in the sanitary state both of villages and premises during the year, but some of the nuisances complained of can hardly be dealt with until some permanent measures of sewerage are found practicable in some of the more low-lying localities. This is the case, for example, as regards the discharge of sewage into the watercourse passing through Clewer Manor and the ditch at the side of Lover's Walk. Both diphtheria and small-pox cases occurred in the Windsor rural district, thus reminding the sanitary authority of the need for providing some permanent accommodation for the isolation of first attacks of infectious diseases. Had the warning been heeded, some of the existing troubles which have fallen upon the district might have been avoided.

Ulverstone Urban District.—The annual death-rate for 1885 was 19·4 per 1000, a by no means small rate for so small a district. In the autumn an extensive epidemic of sore-throat prevailed in a private school, and some of the cases were admittedly diphtheria. The disease also spread into adjoining sanitary districts. The ash-pit question needs very serious consideration. The structures are so contrived as necessarily to induce the maximum amount of nuisance. Sunk below the level of the surrounding soil, they admit of the soakage into them of surface water; being uncovered, they are open to rainfall, and wetness of contents being thus brought about, rapid decomposition is ensured, and a nuisance is created. Reconstruction of the receptacles, limitation of their capacity, and frequent scavenging arrangements are called for. New public slaughter-houses were to have been constructed, but after local inquiry the scheme was, for some reason or other, not sanctioned.

Ulverstone Rural District.—Dr. A. Thompson reports a death-rate of 16·0 per 1000 in this district. In several portions of the area water-supply and means of drainage are still urgently called for; but there is, at the same time, a record of good work, especially where the prevalence of infectious disease easily admits of intervention. It is evident that much work remains to be done in the direction of educating people to understand that there is real danger in the proximity of shallow wells and privies, which by soakage contaminate the surrounding soil.

Maidstone Urban District.—The death-rate of this borough during 1885 was 15·8 per 1000 living. Maidstone was several times invaded by small-pox imported from the metropolis; but the authority having provided themselves with an excellent hospital, that which would otherwise have threatened to produce a serious epidemic was held within reasonable limits. In all, the hospital received during the year 39 cases of small-pox, 3 of scarlet fever, and 2 of diphtheria. The only thing which the hospital is now stated to lack is some separation ward for doubtful or special cases. In connexion with the small-pox outbreaks, it is noteworthy that the only two children attacked were unvaccinated ones, notwithstanding during the past four years some 4000 children have been born in Maidstone. The fact is that vaccination has practically protected our infantile population, which formerly suffered so severely from this disease. Great improvements have been effected in the public water-service of the borough, and Mr. Adams takes the opportunity of this occurrence to point out some important considerations in regard to suspicious waters, and especially to indicate the need for watchfulness whenever any water is found to have departed, in its chemical composition, from the natural local standard, even slight deviations from the normal leading to the detection of pollution, when ordinary chemical evidence alone would fail even to raise a suspicion.

Grange Urban District.—Owing to the existence of fatal enteric fever, privies and water-supply were found to be in such relationship as obviously to constitute grave danger to health. It is unfortunate that in so many instances cases of this sort are, in numberless districts, not dealt with until after disease and death occur. They point to the need for periodical house-to-house inspection, and the maintenance of a record of the sanitary circumstances of all premises in the district. Such inspection, if properly carried out, is perhaps of all sanitary work, the most valuable. Dr. Thomson urges improved arrangements for the scavenging of the district, the provision of better cemetery accommodation, and a system of drainage in the place of a system which admits of the sewage being first stored in cesspools, and thence allowed to percolate into the soil or into the crevices of the limestone rock. Grange is said to possess all the natural advantages of a health-resort, but it certainly lacks the sanitary requirements of such a place. On a small population of 1200, the annual death-rate was 10·8 per 1000, but including visitors it reached 17·5.

Cardiff Urban District.—Dr. Paine commences his report for 1885 with a highly interesting history of cholera as affecting that borough up to 1866, the experience of Cardiff being shown to prove that, by increased sanitation, cholera is robbed of its chief terrors. In 1849 all the insanitary circumstances then attaching to towns generally obtained widely in Cardiff, but at the last outbreak in 1866 the disease was at once met and checked by improved sanitation and water-supply. So also, it is shown, in a tabular form, that the death-rate from the seven zymotic diseases has fallen during the four last decenniads from 9·8 to 5·4, then to 3·9, and in 1875-84 to 3·3. In the same way, the history of the borough with regard to infantile diarrhœa is traced through a series of years; the difference of feeding children with breast milk or with cow's milk and other diets being entered into at some length. Next follow chapters on the local meteorology, house inspections, food supplies, the water service, the dwellings of the working classes, and similar subjects affecting the health of the population. Indeed, the report is an admirable summary of the sanitary history of the borough, both as regards the past and at the present date. The death-rate during 1885 was 25·6 per 1000 on the estimated population, but only 23·1 on the inhabited houses estimate. This is a high rate, and it was mainly due to the prevalence of infantile diseases, a subject which is dealt with in some detail. Infants suffered especially from diarrhœa, 69 out of a total of 99 diarrhœa deaths occurring under one year of age; and amongst other conditions favouring this mortality, it is shown how temperature and rainfall influence it. Such general current work as disinfection, abatement of nuisances, inspection of bakehouses, cowsheds, dairies, and milk-shops,

and the supervision of common lodging-houses, of the food supplies, &c., were continued during the year, and the inspectors of nuisances are credited with considerable zeal and activity in the performance of these several duties.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns 5494 births and 3497 deaths were registered during the week ending August 28th. The annual death-rate in these towns, which had been 18·9 and 19·5 per 1000 in the preceding two weeks, further rose last week to 20·1. During the first eight weeks of the current quarter the death-rate in these towns averaged 19·7 per 1000, and was 1·8 below the mean rate in the corresponding periods of the ten years 1876-85. The lowest rates in these towns last week were 13·9 in Bristol, 15·7 in Plymouth, 16·6 in Bradford, and 17·4 in Hull. The rates in the other towns ranged upwards to 24·9 in Salford, 25·4 in Cardiff, 25·6 in Newcastle-upon-Tyne, and 26·8 in Preston. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 717 and 806 in the preceding two weeks, declined again last week to 778; they included 562 from diarrhœa, 57 from measles, 19 from scarlet fever, 48 from whooping-cough, 35 from "fever" (principally enteric), 27 from diphtheria, and not one from small-pox. The lowest death-rates from these zymotic diseases were recorded last week in Plymouth Huddersfield, and the highest in Cardiff, Salford, and Preston. Diarrhœa caused the highest death-rates in Sheffield, Birkenhead, Salford, Preston, and Leicester; measles in Preston and Blackburn; scarlet fever in Cardiff, Derby, and Salford; whooping-cough in Norwich and Preston; and "fever" in Cardiff and Portsmouth. Small-pox caused no death either in London and its outer ring or in any of the twenty-seven large provincial towns. No small-pox patients were under treatment in the metropolitan asylum hospitals situated in and around London. The deaths referred to diseases of the respiratory organs in London, which had been 150 and 151 in the preceding two weeks, rose last week to 160, but were 13 below the corrected average. The causes of 68, or 1·9 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Norwich, Leicester, Nottingham, Bradford, and in five smaller towns. The largest proportions of uncertified deaths were registered in Salford, Sheffield, Halifax, and Oldham.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 17·4 and 17·9 per 1000 in the preceding two weeks, declined again to 17·7 in the week ending August 28th; this rate was 2·4 per 1000 below the mean rate during the same week in the twenty-eight English towns. The rates in the Scotch towns last week ranged from 13·1 in Perth and 13·7 in Dundee, to 19·9 in Aberdeen and 23·4 in Paisley. The 436 deaths in the eight towns showed a decline of 5 from the number in the previous week, and included 36 which were referred to diarrhœa, 19 to whooping-cough, 16 to scarlet fever, 6 to "fever" (typhus, enteric, or simple), 3 to measles, 3 to diphtheria, and not one to small-pox; in all, 83 deaths resulted from these principal zymotic diseases, against 63 and 72 in the preceding two weeks. These 83 deaths were equal to an annual rate of 3·4 per 1000, which was 1·1 below the mean rate from the same diseases in the 28 English towns. The deaths referred to diarrhœa, which had been 18 and 23 in the previous two weeks, further rose last week to 36, of which 14 occurred in Glasgow, 8 in Dundee, and 4 in Paisley. The annual death-rate from diarrhœa in these Scotch towns last week did not, however, average more than 1·5 per 1000, whereas the mean rate from the same cause in the twenty-eight English towns was 3·2. The 19 fatal cases of whooping-cough showed a slight decline from recent weekly numbers, and included 18 in Glasgow. The 16 deaths from scarlet fever exceeded by 8 the number in the preceding week, and included 12 in Glasgow and 2 in Edinburgh. The 6 fatal cases of "fever" showed a slight further increase upon the numbers recorded in the preceding two weeks; 3 occurred in Glasgow and 2 in Paisley. Of the 3 deaths referred to diphtheria 2 were returned in Edinburgh and 2 fatal cases of measles occurred in Leith. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 61 and 59 in the preceding two weeks, rose again last week to 67, and exceeded by 12 the number in the corresponding week of last year. The causes of 62, or more than 14 per cent., of the deaths in the eight towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which in the preceding four weeks had risen from 17·3 to 21·9 per 1000, declined again to 18·2 in the week ending Aug. 28th. During the first eight weeks of the current quarter the death-rate in the city averaged 20·0; the mean rate during the same period was 20·0 in London and 18·2 in Edinburgh. The 123 deaths in Dublin last week showed a decline of 25 from the number in the previous week, and included 9 which were referred to diarrhœa, 5 to "fever," 3 to scarlet fever, 1 to whooping-cough, and not one either to small-pox, measles, or diphtheria. These 18 deaths from the principal zymotic diseases showed a decline of 3 from the number in the preceding week, and were equal to an annual rate of 2·7 per 1000, the rates from the same diseases being 3·7 in London and 1·4 in Edinburgh. The 9 fatal cases of diarrhœa, and the 5 deaths referred to different forms of "fever," corresponded with the numbers in the preceding week, while the deaths from scarlet-fever showed a slight decline. Two inquest cases and 4 deaths from violence were registered; and 29, or nearly one-fourth of the deaths, were recorded in public institutions. The deaths of infants showed a decline from the number in the previous week, while those of elderly persons showed a slight excess. The causes of 18, or nearly 15 per cent., of the deaths registered during the week were not certified.

THE SERVICES.

WAR OFFICE.—Army Medical Staff: Surgeon-Major George Bedford Sanders is granted retired pay, with the honorary rank of Brigade Surgeon.

The undermentioned Surgeons on probation to be Surgeons:—John Stewart Davidson, M.B.; James Will, M.B.; James Moir, M.B.; James Fallon; John Valentine Salvage, M.B.; John Francis Scott Fowler, M.B.; Arthur Russell Aldridge, M.B.; Robert Ashton Bostock; Joseph Fayrer; Charles Pope Walker, M.B.; Charles Joseph MacDonald, M.D.; Charles John Willmer Tatham; Thomas Harry Fredk. Clarkson; Herbert Ward Austin; Cathcart Garner, M.B.; Robert Wallace Wright; William Frederick Bailey, M.D.; Edwin Eckersley, M.B.; Reginald James Cope Cottell; John Gillespie Deacon, M.D.; David Middleton Greig, M.B.; James Rogers Burrows, M.D.; John Keatly; Daniel Hennessy, M.D.; David Michael Saunders, M.D.; Walter Kiddle, M.B.; Denis Moriarty O'Callaghan; Michael Joseph Whitty, M.D.; Henry Alfred Cummins, M.D.; Richard Edmund Kelly, M.D.; James Francis Donegan; John Donaldson; Hugh Broderick Mathias; George Bent; George Henry Barefoot; Foster Reuss Newland, M.B.; Reginald Joscelyn Windle, M.B.; Robert John Draper Hall; Edward Swan Marder; Charles William Allport, M.D.; John Joshua Russell, M.B.; Arthur Joseph John Simpson Edye; George Scott, M.B.; Thomas Browning; Albert L. F. Bate; William John Trotter; Andrew Hosie, M.B.; George Frederick Handel Marks, M.D.; Ralph Holyoake; Robert Napier Buist, M.B.; John James Carl Watson, M.D.; Thomas Whaite, M.B.; Henry Thomas Knaggs; Ferdinand Simeon Le Quesne; Victor Edwin Travers-Smith, M.D.; Norman Smyth, M.D.; Cecil Spencer Cronin; Willington Dowman; and Richard Ernest Foott, M.D.

ADMIRALTY.—The following qualified candidates for the Naval Medical Service have been appointed to be Surgeons in Her Majesty's Fleet—viz.: George Henry Foote, M.D.; Hamilton Edward L. Earle.

The following appointments have been made:—Staff Surgeon James D'A. Harvey, to the *Boscawen*; Staff Surgeon Alexander Flood, to the *President*, additional, for temporary service; Fleet Surgeon Thomas H. Atkinson, to the *Duncan*, additional; Staff Surgeon Charles C. Godding, to the *Northampton*, additional, for temporary service; Surgeon John F. Bate, to the *Pembroke*, additional; Surgeon Graham E. Kennedy, to the *Royal Adelaide*, additional; Surgeon John

E. Webb, M.B., to the *Lion*, additional; Surgeon Martin H. Atock, M.D., to the *Indus*, additional; Surgeon James J. M'Donnell, to the *Defiance*; Surgeon Charles E. Geoghegan, to the *Asia*; Surgeon East Arthorpe, to the *Excellent*, additional; and Surgeons George H. Foote, M.D., and Hamilton E. L. Earle, additional, to the *Duke of Wellington*, for Haslar Hospital; Staff Surgeon Charles L. Vasey, to the *Britannia*, additional, for temporary service.

ARTILLERY VOLUNTEERS.—4th Lancashire: Thomas Babington Grimsdale, Gent., M.B., to be Acting Surgeon.

Correspondence.

"Audi alteram partem."

HÆMATOCELE, INTRA- OR EXTRA-PERITONEAL?

To the Editor of THE LANCET.

SIR,—The point raised in Dr. Lewers' letter, published Aug. 28th, is the *crux* of the question of hæmatocele. Such cases as he describes are common enough, and the great majority of them recover, because they are cases of hæmorrhage into the broad ligament—extra-peritoneal hæmatocele. In that most valuable and most strangely neglected book by Bernutz and Goupil there is abundant evidence from the post-mortem table, enough to settle the question, it seems to me; but the evidence now derived from abdominal section places it beyond dispute, and this evidence I hope shortly to present to your readers in the Ingleby lectures, for which you have kindly given me space in your columns.

Let me for the present only point out to Dr. Lewers that the fact he puts on record, that "sometimes the tumour is large enough to be felt through the abdominal wall above the pubes," is enough to settle the point, for the tumour so felt must be the distended broad ligament; how could an unlimited clot be felt as a tumour? When hæmorrhage occurs free into the abdominal cavity, it does not form a tumour, but is found as bloody serum and loose fragmentary clot all about the cavity, and has in every one of my cases given rise to fluctuation, the sign of effusion, and a vague uncertain dulness on percussion—precisely what was described in Dr. Imlach's case. When hæmorrhage occurs into the broad ligament, a firm rounded tumour distinctly limited is produced, such as Dr. Lewers describes. Extra-peritoneal (or broad ligament) hæmatocele is very common, and its most common method of production is precisely what Dr. Lewers speaks of—an abrupt arrest of menstruation. Of this variety probably 95 per cent. of the cases get well by being left alone, whilst the others suppurate and require to be opened. I used to open them by the vagina, but now I open them by abdominal section, with far better results. It is these operations which enable me to speak quite positively in support of the pathological facts so well and so carefully recorded by Bernutz and Goupil.

I am, Sir, yours truly,

Birmingham, August 30th, 1886. LAWSON TAIT.

CASEY *v.* IMLACH.

To the Editor of THE LANCET.

SIR,—While an "unwilling witness" in the case of Casey *v.* Imlach, Dr. Grimsdale stated on oath that the mortality in cases where this operation (i.e., abdominal section) had been performed at the Hospital for Women was 33 per cent. (*Times*, Aug. 9th).

I have performed abdominal section for pelvic hæmatocele eighteen times at our hospital, and am the only one that has performed it. All of the patients fully recovered from the operation, and seventeen of them are at the present moment alive and well. Six of these operations occurred in 1884, and five of them were reported in full detail in the *British Medical Journal*, May 16th, 1885. Mrs. Casey was the sixth. Her case was not published because I had forwarded my paper to the journal before she entered hospital, but your readers are now familiar with it. In 1885 I performed this operation nine times, and all recovered; but one with morbus cordis died subsequently from causes entirely unconnected with her operation, and the circumstances were fully reported in a paper on pelvic hæmatocele published in the *British Medical Journal* of Feb. 20th, 1886. In the present year I have performed abdominal section three times for this condition; all have recovered, and the parts removed in the last of them (Aug. 27th) are now in the hands of Dr. Barron, pathologist to the Royal Infirmary, for examination. I find from my note-books that I have met with hæmatosalpinx, without intra-peritoneal hæmorrhagic effusion, about fifteen times. The indications for operation in these cases are entirely distinct from those of internal hæmorrhage which prompt us to interfere in pelvic hæmatocele. In general, hæmatosalpinx is associated with some other pathological conditions, and many cases are entered in our report as "myoma hæmorrhagica with occluded tubes," &c. When the patient is blanched it is only because of prolonged menorrhagia, and sometimes the chief symptoms are constant pelvic pain and inability to walk or work.

I find in the report for 1885 two fatal cases entered as hæmatosalpinx. One of these was complicated, not with intra-peritoneal hæmorrhage, but with a rectal abscess with which the tube communicated; and to class such cases with pelvic hæmatoceles is simply misleading. In any case these two are the only fatal results by which Dr. Grimsdale can make out that the operation in both classes of cases is attended with any mortality whatever. He carefully excludes from his statistics the case of Mrs. Casey and the whole series of pelvic hæmatoceles of 1884. He excludes also a successful case of operation for hæmatosalpinx in 1884, and another in 1885. He confines his attention to the report for 1885, and gravely miscounts its numbers. He includes two cases labelled hæmatosalpinx, but excludes a third, in which health was completely restored, and he is careful to include as a fatal operation the case of hæmatocele which fully recovered from the operation, but died under circumstances already referred to. But this goes beyond manipulation of figures, and will reflect upon himself the odium which he vainly endeavours to attach to a valuable means of saving life.

I am, Sir, yours obediently.

Liverpool, Aug. 31st, 1886. FRANCIS IMLACH.

"SPAYING."

To the Editor of THE LANCET.

SIR,—With your permission I should like to make a few remarks on one portion only of Mr. Lawson Tait's letter in your issue of August 21st. I mean that part in which Mr. Tait objects to the use of the word "spaying," as synonymous with the phrase "removal of the uterine appendages." He considers this an "extraordinary confusion of terms," and gives the following as his reasons and conclusions therefrom as regards spaying. 1. "Animals," he says, "are spayed before puberty to prevent its access, and the consequent development of a sexual appetite and powers, and the powers of procreation." 2. "The ultimate object of the process of spaying is an improvement in our food-supply, or in our domestic service by animals." As regards removal of the human uterine appendages: 1. This operation "is performed after puberty, generally long after puberty." 2. "It has no influence, as far as I know, in destroying the sexual powers; indeed, it constantly restores them, after disease has destroyed them." 3. "It does not usually destroy the procreative power, for that (in the great majority of instances) has been already destroyed by the disease for which the operation has to be performed." 4. "Finally, the operation has no other purpose than the saving of life and the relief of suffering. The operation of spaying an animal and the removal of the human uterine appendages have therefore no conceivable resemblance. Consequently to talk of 'spaying women' is to display great ignorance or to indulge in wilful misrepresentation for purposes of giving offence." Now these appear to me to be very extraordinary reasons for Mr. Tait's objections to the use of the word "spaying," and still more extraordinary are the conclusions which he draws from his premisses. Mr. Tait does *not* say that a certain operation (female castration) called "spaying," when performed on an

animal, should have another name when performed on a woman; if he did, his argument would at least be intelligible. But what he really does say, and what the sum of all his arguments amounts to, is this, that the question whether the name of this operation "spaying" should when performed on a woman be altered depends on the following conditions:—1. The time of life at which it is performed. 2. The reasons for its performance. 3. The objects contemplated in its performance. And Mr. Tait finding none of these conditions the same in the woman as in the lower animals, not only insists that the name of the operation itself must be changed, but finds no conceivable resemblance between these operations. How Mr. Tait comes to the conclusion that the operation of spaying an animal and the removal of the uterine appendages in a woman—consisting, as these operations do, of the removal of the corresponding organs in each—have therefore no conceivable resemblance is quite beyond my powers of reasoning. And his final "consequently to talk of 'spaying women'" makes me fear that I am "displaying great ignorance," but I am quite sure I am not indulging "in wilful representation for purposes of giving offence."

I should be very sorry to impute any such ignorance, or any improper motives whatever, to those gentlemen who prefer always to use Mr. Tait's favourite phrase, "removal of the uterine appendages," to the more expressive, shorter, and better known name of "spaying"; but I would humbly submit that when writing or speaking on this subject to the profession, Mr. Tait's phrase answers every purpose; but when writing or speaking to lay people, the older and shorter term "spaying" is more suitable, as being better "understanded of the people." And if it be agreed on all hands, as I presume it is, that a full and complete explanation of the nature and consequences of these operations should in every case be previously given to the patient and her nearest relative, then I think even Mr. Tait will admit that no simpler, no surer, method could be found for making all, even the more ignorant class of people, fully understand what is about to be done to them, than for the operator to say, "You must be spayed," or "I am going to spay you." This I take to be a great and unmistakable advantage, and I shall therefore continue to adopt the older, simpler, and more expressive term, and call a "spay" a "spay" when speaking to all those who, not being in the profession, even if decently educated, get but a hazy and indistinct idea from the more novel and more sonorous, but not very expressive phrase, "removal of uterine appendages."

One might go even a little further, and say that the final word "appendages" hardly expresses, or gives a hint of, the highly important character and functions of these organs; indeed, it would seem, as it strikes upon the ear, to give the idea of some comparatively unimportant additions to the important organs of gestation—the uterus and womb. This I consider to be a decided drawback to its general use now that the operation has come to be talked about freely in non-professional circles.—I am, Sir, yours truly,

August 23rd, 1886. THOMAS F. GRIMSDALE.

THE DIRECT REPRESENTATION OF THE PROFESSION.

To the Editor of THE LANCET.

SIR,—In recognition of the extreme importance that must attach to the selection of suitable representatives of the great body of English and Welsh medical practitioners on the General Medical Council, and feeling that such a selection cannot be well made by individual effort, a number of medical men from all parts of the kingdom have formed themselves into a committee with the single object of trying to arrive at something like a general consensus of opinion as to who are the best men to select. It is sufficiently indicative of the widespread interest that is felt in its action that the committee embraces among its members representative men from almost every large town in England and Wales; and what is, perhaps, of more significance still, from many of the smaller towns and villages; and as it is most desirable that the profession generally should be made fully aware of its aims, I venture to ask your insertion of this letter.

The committee is absolutely uncommitted to the support of any candidate, its sole object being to deliberate impartially on the claims of all, and ultimately to recommend to the consideration of the profession the three into whose hands it would appear to them to be safest to entrust the interests of that large body of the general practitioners of this division of the United Kingdom hitherto unrepresented on the General Medical Council. As the committee is bound to no candidate, so is it confined to no party, and with the view of making the ultimate selection a thoroughly satisfactory one it will hail with great satisfaction every suggestion that can be offered to it. Letters approving of its object, many of them containing suggestions of great practical value, have already been sent from every part of the kingdom. Some of these letters suggest the names of candidates, and it is proposed that every name thus mentioned shall be carefully considered. As the committee wishes to embrace every interest of the general practitioner, it is desired that all who agree with its objects shall associate themselves as members, and shall assist either by letter or personal attendance at its deliberations. It is proposed to hold a meeting at the Queen's Hotel, Birmingham, at 5 P.M. on Tuesday, Sept. 14th, to go over names. The honorary secretaries are Dr. William Carter of Liverpool, and Hugh R. Ker, Esq., F.R.C.S., Halesowen, Worcestershire, either of whom will gladly receive communications from any member of the profession desirous of joining the committee.

I am, Sir, yours faithfully,

Liverpool, Aug. 20th, 1886. WILLIAM CARTER.

DRY ANTISEPTIC POWDER.

To the Editor of THE LANCET.

SIR,—In your issue of the 21st inst. you note a form of antiseptic dressing by carbolised paper. For many years I have been in the habit of using a dry antiseptic powder in much the same way: oxide of zinc, carbonate of magnesia, and powdered boracic acid, with carbolic acid added so long as the powder retains its character as a powder. This dusted over the surface of a wound—an old indolent ulcer or a scald—at once reduces the discharge from the surface and renders it of a healthy nature. No matter how extensive the surface may be, it does not require to be cleaned off at any time, the only dressing requisite being to continue the dusting; in extensive burns or scalds the relief from painful dressing is very marked. In indolent ulcers a piece of old linen rag must be placed over the powder, and pressure exercised by means of an indiarubber bandage. In ulcers of the penis the carbolin of oxide of zinc, with resorcin and calomel added, forms a dressing which rapidly heals. I used the dry antiseptic dressing recently to dress the wound caused by the operation for strangulated inguinal hernia; it acted perfectly, there was not one drop of pus secreted, the wound healed by the first intention, and the patient was discharged from hospital in eight days. "Portability" is of great importance, and this powder is easily carried. A small receptacle similar to a pepper-box serves to dust the wound with. I have used a compound box which, being in form much the same as an ordinary round ruler, is easily carried, and contains chambers for four or six different powders. In specific ulcers, and where there is an unhealthy surface, it is advisable to destroy that surface with nitric acid or nitrate of silver before using the powder.

I am, Sir, yours truly,

Sheerness, Aug. 21th, 1886. PERCIVAL HUNT, F.R.C.S.E.

"THE MEDICAL ACT OF 1886."

To the Editor of THE LANCET.

SIR,—I am very much amused with the letter of "An M.D. of New York." He must know how easily an M.D. is obtained in America, and I think that no greater mistake was ever made than to admit foreign diplomas to the Medical Register. I have been a ship-surgeon, and have visited some of the American universities and medical colleges, and have formed a very low estimate of them. In fact at one of the universities in a Southern State I was informed by one of the professors that they could undertake to take a man off the cab-stand and make an M.D. of him in a few months, and I know of a case where an uneducated working man left England a few years ago, and, after being a short time in America, returned home with the degree of M.D., U.S.A. I

think the new Medical Act will do more harm to the medical profession in England than any Act that has ever been passed, and it will undoubtedly lower the status of every member of the profession, and the overcrowding will be increased. I have written to two members of Parliament in reference to the registration of foreign diplomas. One of them replied as follows:—"It is notorious that foreign diplomas may be had on easy terms, and it is unfair to class them as equal to our own." The other member answered my letter thus:—"I ascertained that the leading members of the medical profession do not object to these being registered provided this is done in a separate list, so that there may be no confusion between British and foreign diplomas." The holders of foreign diplomas will not care for this so long as they can tell the public that they are on the Medical Register, and as to the opinion of the leading members of the profession, Medical Bills do not affect them as they do the mass of the profession, the general practitioners; and every Bill brought in ought to be on behalf of the profession; and although in the new Medical Bill the general practitioners have gained five representatives, they have paid too dearly for it in allowing foreign diplomas to be registered. I have no personal interest in this matter, as I have been a good many years in the profession, and have realised a competency, and have a good social and professional position; but for the sake of the rising young members of the profession who have been required to pass severe examinations, and who have to contend with an overcrowded profession, I do not see that they should be still further overweighted by admitting foreign diplomas, and I advise them to be up and doing, and interview their member of Parliament, and ask him to use his influence to repeal the clause bearing on foreign diplomas.

I am, Sir, yours truly,

A GRADUATE OF A SCOTCH UNIVERSITY.
(Possessor of three English and three Scotch diplomas, all of them registered.)

August 30th.

To the Editor of THE LANCET.

SIR,—Your correspondent, "An M.D., of New York," in contrasting an American degree with the M.D. Brussels, asks which is the more reliable qualification. I unhesitatingly say the M.D. Brussels; for, according to the rules of the Brussel's University, none but qualified practitioners are admitted to its examinations. This in itself is a guarantee that all candidates for its degree are men who have spent at least four years at a recognised medical school, and have successfully undergone the various examinations at some one or other licensing board and evinced their fitness to practise prior to their degree examination. When I add that out of these picked and qualified men at least from 30 to 50 per cent. are invariably rejected, it goes without saying that the lame, the halt, and the failures of other universities and corporations, who are apt to knock from door to door until they find an indulgent *alma mater*, have no place whatever here. Men selected and approved by a searching examination from amongst already British qualified practitioners, whose very qualifications bespeak a certain amount of knowledge and training, can only secure the degree, for M.D. Brussels not only implies a higher examination, but a British qualification as well. Can "An M.D. of New York" claim as much for an American degree?

I am, Sir, yours faithfully,

Aug. 28th, 1886. AN M.D. OF BRUSSELS.

THE INCUBATION PERIOD AND DURATION OF INFECTIOUSNESS OF DIPHTHERIA.

To the Editor of THE LANCET.

SIR,—Your correspondent, Dr. Pearse, is mistaken in saying that "no observations seem to be recorded" as to the incubation period of diphtheria. In a paper contributed by me in 1878 to the St. George's Hospital Reports (vol. ix., p. 711) are recorded three cases in which an attack of diphtheria followed a single exposure to a source of infection; in one the incubation period was two days, in a second four days, and in the third five days. In that same paper are also recorded eight other cases in which the exposure to possible infection had not been limited to a single occasion, so that only the outside limit of the incubation period could be determined; in none of these eight cases did the interval between the first exposure and the attack exceed a week, being in three cases two days, and in single cases one, three, five, six, and seven days severally. In one other case there was reason to believe that the incubation period was at least eleven days.

In the same paper will be found several observations as to the duration of infectiousness of diphtheria—that is, as to the time during which a person who has had diphtheria is capable of communicating the disease to others, and these observations appear to me to show conclusively that the infectiousness attaches to a patient for a much longer period than three weeks, which is the term assigned to it by Dr. Pearse.

I am, Sir, yours obediently,

WILLIAM OGLE.

Gordon-street, Gordon-square, Aug. 31st, 1886.

To the Editor of THE LANCET.

SIR,—Dr. Pearse fixes the incubation period of diphtheria at fourteen days. Two years ago I had two cases under my care, in which I found it to be two days only after exposure to the poison. Other practitioners will no doubt be able to calculate the period in cases they have treated. The treatment I have found most efficacious in cases of this nature is that by the biniodide of mercury in solution of potassic iodide, followed, on disappearance of the membranous effusion, by steel and chlorate of potash. Thus: Solution of bichloride of mercury, one ounce; iodide of potassium, half a drachm; citrate of ammoniated iron, one drachm; chloric ether, two drachms; water to eight ounces. One tablespoonful every two hours. I am, Sir, your obedient servant,

Clayton-le-Moors, Aug. 29th, 1886. C. R. ILLINGWORTH, M.D.

To the Editor of THE LANCET.

SIR,—In your issue of August 28th two cases are cited in which the incubation period of diphtheria would appear to have been about forty-eight hours. In connexion with the same subject I send you a note recorded about three years ago:—

F. B——, one of a numerous family, had a very severe attack of diphtheria. The other children were at once removed, and on the patient's recovery the house was well fumigated by the burning of sulphur, and, in addition, there was much washing with carbolic acid. The rooms were also repapered and whitewashed. The patient was sent away, and after he had been absent for twenty-five days three children of the same family were allowed to return. On the eighth day after their return I was called to the house, and found two out of the three with well-marked diphtheritic patches on the throat. They had remained quite well until the previous day.

I am, Sir, faithfully yours,

East Grinstead, Aug. 30th, 1886. JOHN MAGRATH, M.D.

EDINBURGH.

(From our own Correspondent.)

POST-GRADUATE COURSE IN EDINBURGH.

IN a former notice of this course of demonstrations one or two particulars were omitted which have since become more definitely known. In consequence of a statement of their opinion to that effect, it has been decided to adopt the view of the managers of the Royal Infirmary, that no fee should be expected from those who attend the course. Another item of some importance is, that the demonstrations are to be thrown open to all practitioners of medicine, and are not to be confined to graduates of the Edinburgh school, as was at one time in contemplation. In addition to the thirteen clinical and practical courses already alluded to in previous notices, arrangements have now been made for a complete series of demonstrations in bacteriology. These demonstrations, six in number, will be held in the pathological department at the new University Buildings, under the auspices of Professor Greenfield, and will be of as practical a nature as can be made consistent with a fairly exhaustive treatment of the subject. A large number

of inquiries as to the arrangements of the classes have been already received, and numerous intimations of their intention to be present, from medical practitioners at a distance. The committee, however, are anxious that all who intend to take part in the course should communicate their intention as soon as possible to one or other of the secretaries—Dr. Muirhead and Professor Chiene (Charlotte-square), so that adequate arrangements for their reception may be completed.

THE CITY FEVER HOSPITAL.

After a prolonged period of waiting, the Town Council have at length resolved to give effect to the repeated recommendations of the city medical officer of health and vote a reasonable sum as an honorarium to the visiting physician to the City Fever Hospital. This decision has been rapidly followed by the appointment of a well-known Edinburgh physician to the vacant post. Dr. W. Allan Jamieson has accepted the post, and his appointment is one that will give general satisfaction here; and especially so as Dr. Jamieson has in his development of the Dermatological Department of the Royal Infirmary proved himself an able clinical teacher, and is therefore one who may be looked to as a clear exponent of diseased conditions, who will not lose opportunities of imparting instruction as soon as the authorities recognise the absolute necessity of opening their fever wards for the purposes of clinical teaching.

Edinburgh, Aug. 31st.

IRELAND.

(From our own Correspondent.)

THE Chair of Surgery in the Queen's College, Belfast, has become vacant, and applications for the post must be forwarded to the Under-Secretary at Dublin Castle not later than the 7th inst.

THE EPIDEMIC OF FEVER IN HARE ISLAND.

The patients attacked with typhus are doing well, but from a report of Dr. Hadden, dated Aug. 21st, it appears that another woman has contracted the disease, and has been admitted to hospital. One of the nursing sisters also has caught the infection, and has been removed to Skibbereen. The notice of motion given by one of the guardians of Skibbereen Union, that a medical man should reside on the island, has been withdrawn, as the proposed arrangement could not be carried out.

ROYAL UNIVERSITY OF IRELAND.

The Senate will, at its meeting in October, consider the appointment of one Fellow in the department of Medicine. The salary will be £100 a year, provided always that if any medical Fellow shall hold any fellowship or professorship in any other university, or college, he shall receive only such sum, not exceeding £100 yearly, as with the salary of the other fellowship or professorship shall amount to £400 per annum. The office is tenable for seven years, and the Senate appoint by open voting. As regards the duties to be performed, every medical Fellow holds his fellowship upon condition that he shall act as an examiner at the medical examinations of the University, and shall be bound, in conjunction with any other persons whom the Senate may add, to conduct the medical examinations of the University without further payment, save for expenses. It is probable that the contest for a member of the Senate, in the vacancy caused by the decease of Mr. Curtis, will mainly lie between Dr. Whitla, and Major Fitzgerald, a distinguished graduate of the University.

STROKESTOWN DISPENSARY.

In consequence of the sudden death of Dr. Murray, an election for a medical officer took place last week, and Dr. Duffy was appointed by a majority of votes. So great was the excitement in connexion with the election that the authorities considered it advisable to draft a number of extra police into the town from Athlone and other places.

LUNACY IN IRELAND.

The report for 1884 was not issued until February last, but the inspectors of lunatic asylums in Ireland on this occasion have published their report for 1885 with greater punctuality. A total of 14,279 persons were registered as being mentally affected at the beginning of last year; in the course of which, in addition to 9687 being located in district asylums, 2850 cases were admitted. Of these latter, 2240 were cases of first attack, and 610 relapses. From the proportion of recoveries on the daily average of patients, it would appear that about eighteen individuals in every 100 were directly benefited in a curative or ameliorative point of view from district asylum treatment; but if estimated on the basis of admissions, at about 53 per cent. The deaths numbered 856, and were somewhat lower than those which occurred in the previous year; four of these were suicidal. The inspectors justly refer to the inadequate pay and allowances granted to the subordinate resident staffs attached to district asylums, and they are of opinion that their position admits of a more liberal consideration, taking into account the irksome, responsible, and not infrequently dangerous occupations in which they are unceasingly engaged. The cost of supporting district asylums last year was £216,799 17*s.* 4*d.*, or at the rate of £21 19*s.* 5*d.* per inmate, being a decrease of £1 1*s.* 6*d.* per head as compared with the previous year. In poorhouses, 3733 persons, composed of lunatics, aged, utterly demented and tranquil, were located last year. Latterly, at some union boards, a strong feeling has been expressed that the insane of all denominations should be transferred to district asylums—a scheme which, if carried out, would entail a large outlay on new buildings, or on extensive additions to the existing ones, independent of an increased local taxation and a fresh call on the Government rate in aid. Some years ago it was proposed to erect large provincial receptacles for idiots, epileptics, and demented lunatics, but the project was abandoned from the likelihood of its failure. In the inspectors' report they state their objection to these depôts, as, independent of the outlay for their construction, the number of counties and cities attached to them would cause much embarrassment in their working, with continuous and unavoidable expenses and inconveniences consequent upon the conveyance and return of patients at the desire of their friends to and from remote localities, distant perhaps 100 or 130 miles. The full establishment cost of each for 800 or 1000 inmates might be reasonably estimated at from £25,000 to £30,000.

Dublin, Aug. 31st.

MEDICAL NOTES IN PARLIAMENT.

The Ventilation of the House.

IN the House of Commons on the 26th ult., Mr. Plunket, in reply to Mr. R. Cooke, said the Committee on the Ventilation of the House had been reappointed, and had held its first meeting. He was authorised to state that they were satisfied with the recommendations in the second report of the previous select committee. These recommendations would be carried out with as little delay as possible, and he hoped the works would be completed before the reassembling of Parliament.

The proposed Small-pox Hospital.

On the 27th ult. Mr. Pickersgill, who had given notice to ask the President of the Local Government Board whether he had received protests from several metropolitan boards of guardians against the proposal of the Metropolitan Asylums Board to erect a permanent small-pox hospital at Gore Farm, Darenth, at an estimated cost to the ratepayers of £116,000; whether he was aware that it was proposed to hold a conference of the metropolitan guardians at an early date to consider the question; and whether he would withhold the assent of the Local Government Board to the proposed expenditure, at all events until this conference had been held,—said he had now been informed that the Local Government Board had refused its assent. He wished to know if that was correct. In reply, Mr. Ritchie stated that it was quite correct.

The Metropolitan Asylums Board.

On the 30th ult., in reply to Mr. Pickersgill, Mr. Ritchie stated that it is the fact that the accommodation provided for imbecile children by the Metropolitan Asylums Board is at present insufficient for the needs of the metropolis. The managers are now, however, extending the schools for imbecile children at Darenth, and he understood that the buildings will be completed this summer. It is expected

that, when finished, they will afford the accommodation required for children of this class. The managers have an asylum at Hampstead which is not at this moment occupied, but in the event of any serious increase of fever in the metropolis it would no doubt be necessary to use that asylum for fever patients.

Unlicensed Practitioners.

On the 2nd inst., Sir T. Esmonde asked whether it was a fact that there were at present a large number of so-called medical practitioners practising in London whose names did not appear on the Medical Register; and if it were a fact that several persons had been recently poisoned by them; and if so, what steps would be taken by the Government in the matter.—Sir H. Holland stated, in reply, that there was no information with the Privy Council Office to support the inference in the hon. gentleman's question. No doubt there were many unregistered persons practising in London who would be liable to prosecution. The Government did not think it necessary to take any steps in the matter, though their attention would be given to any case brought under their notice.

Medical News.

NAVAL MEDICAL SERVICE.—At the competition for commissions in the Medical Service of the Royal Navy, held on Aug. 9th and following days in the Hall of the University of London, the undermentioned gentlemen were the successful candidates:—

	Marks.		Marks.
Milner, G. H.	2960	Axford, W. G	2265
Weightman, A. E.	2885	Spiller, W. C.	2240

Menary, J....	2270		

SOCIETY OF APOTHECARIES.—The following gentlemen passed their examination in the Science and Practice of Medicine, Surgery, and Midwifery, and received certificates to practise, on Thursday, the 26th ult.:—

Boxall, Frank, Oakley-square.
Brodie, Fredk. C., Fernhill-park, Wootton, Isle of Wight.
Haring, Nathan Charles, Upper Brook-street, Manchester.
Hounsell, Frederick Claud Wright, Woodlands, Torquay.
Jennings, Edgar, Sherriff-road, West Hampstead.
Miller, Frederic Richard, Ivy House, West Firs, Hants.
Orton, F. J. Johnson, Vine Cottage, Longford, near Coventry.
Sawell, Frank Leslie Pownall, Royal-crescent, Holland-park.
Tidey, Stuart Alex., Glenely, Springfield-park, Acton.

At the recent examination for the competitive examination for the prizes in Materia Medica and Pharmaceutical Chemistry, annually given by the Society, the following were the successful candidates:—

Toller, Seymour Graves, St. Thomas's Hospital; Gold Medal.
Cowen, T. Phillip, St. Thomas's Hospital; Silver Medal and Books.

Dr. A. H. N. Lewers has been elected a member of the Court of Examiners, in the room of Dr. Fowler, deceased.

DR. JOHN SAVAGE, the oldest medical practitioner in Newry, Ireland, died last Saturday by a fall from a ladder.

IN consequence of the prevalence of scarlet fever at Dowlais, the Local Board of Health have directed the temporary closure of the public schools in that place.

AT a meeting of the managers of the Metropolitan District Asylums on the 28th ult., the chairman announced the gratifying fact that there was not at that moment a single small-pox patient in any of their establishments.

THE BRITISH ASSOCIATION.—Sir J. W. Dawson, F.R.S., F.G.S., Principal of McGill University, Montreal, delivered his inaugural address at the opening session of this Association at Birmingham on the 1st instant. The subject mainly dealt with was the geological history of the North Atlantic Ocean.

IT is stated that the Queen has signified her willingness to open the Metropolitan Free Hospital in Kingsland-road, on a date which has yet to be fixed. The building is rapidly approaching completion.

AN election for an assistant medical officer to the Richmond District Lunatic Asylum, Dublin, took place last Tuesday. There were a large number of candidates for the post, the governors electing Dr. George P. Cope.

THE Epping Rural Sanitary Authority have agreed to borrow £10,000, to purchase land for the Chingford outfall works, to carry out a scheme of drainage for the district; £2000 to be applied for the purchase of a site, and the remainder for the carrying out of the works.

A NEW edition of Professor Ferrier's treatise on "The Functions of the Brain" is in the press. The book has been almost entirely rewritten. The revised issue will include the results of new investigations by the author, as well as a critical survey of the more important physiological and pathological researches on the functions of the brain and nervous system that have been published during the last ten years.

ACADEMY OF MEDICINE OF PARIS.—At the last meeting of this Society, the Commission charged with the task of selecting candidates for the vacant post of foreign corresponding member, submitted three names to the Academy in the following order:—Dr. Bateman of Norwich, Dr. Ossian Bonnet of Rio Janeiro, and Dr. Crocq of Brussels. The result of the ballot was twenty-three votes for Dr. Bateman and one vote for Dr. Bonnet, the former being consequently declared elected.

DEATH OF ANOTHER PATIENT OF M. PASTEUR.—A child, three years and a half old, is reported, in the *Semaine Médicale* of last week, to have died lately from rabies at Teste. He was bitten by a mad dog on June 14th last. On the 16th, he was brought to Paris, where, during ten days, he was submitted to Pasteur's treatment. After his return to Teste on June 28th, the child was seized on Aug. 12th with the first symptoms of hydrophobia, to which he succumbed in a few days.

ST. JOHN AMBULANCE ASSOCIATION.—Mr. John Furley, Deputy-chairman and Honorary Director of Stores of this Association, has received from the German Samariterverein a diploma, illuminated on vellum, appointing him an honorary member of the latter Society, "in acknowledgment of his services in the universal extension of the knowledge in first aid to the injured, more especially in recognition of the encouragement and assistance given by him towards the establishment of the German Sanitarian Society."

HOSPITAL SATURDAY FUND.—At a meeting of the Board of Delegates of this fund on the 28th ult., the secretary reported that there was now standing to the credit of the fund at the bank £3000, proceeds of the last street collection, after payment of £700 expenses. About £300 remained in the hands of local committees, and a considerable amount in bronze coin was at the central office. Altogether, about £4800 would accrue to the fund from last Hospital Saturday—£500 less than in the preceding year. This was attributed to unfavourable weather. A recommendation of the Council that in October next a special appeal should be publicly made in the name of Lord Brabazon and other vice-presidents of the fund "urging its claims upon all classes" was, after some rather sharp criticism, adopted.

BRITISH PHARMACEUTICAL CONFERENCE. — At the commencement of the sittings of this annual conference on the 31st ult. at Birmingham, the president, Mr. T. Greenish, delivered an address on the inferiority of the British Pharmacopœia, and urged that a strenuous effort should be made to place it on a level with the progress made in pharmacy. The following papers, amongst others, were afterwards read and discussed:—"Crystallised Aconitine," by Mr. J. Williams; "Certain Derivatives of Hymen-Dictyonine," by Mr. W. A. H. Naylor; "A False Pareira Brava," by Mr. W. Kirby; and "A New Antiseptic," by Mr. J. Moss. On the 1st inst. Professor Hillhouse read a paper on the correlation of studies in botany and materia medica, after which it was resolved to undertake the preparation of a formulary of non-official remedies.

A FORTUNATE UNIVERSITY.—Since 1879 the University of Sydney has received donations exceeding a million of dollars. One bequest, known as the Challis bequest, is expected to realise £200,000. The Macleay Natural History collection, another recent gift, is valued at £25,000, and a sum of £6000 has been promised for the endowment of a curatorship in connexion with it. For the purpose of founding a library a donation of £30,000 was made.

THE TRIENNIAL ASTLEY COOPER PRIZE.—This prize of £300 has been gained by Mr. Anthony A. Bowlby. The subject was "Diseases and Injuries of the Nerves, and their Surgical Treatment, together with the operations performed upon Nerve Trunks in the treatment of various diseases, and description of the changes which ensue in other structures as well as in the nerves themselves from these operations."

BOMBAY HOSPITAL FOR WOMEN.—The "Times of India" gives an account of the opening of the Cama Hospital (officered entirely by women) by his Excellency Lord Reay, Governor of Bombay, in the presence of a very large assembly of friends, on July 30th. The foundation stone of the hospital had been laid in November, 1883, by his Royal Highness the Duke of Connaught. In opening the hospital, Lord Reay remarked that there was no movement in India in which Her Majesty felt greater personal interest.

THE WATER-SUPPLY OF THE METROPOLIS.—In his report of the examination of the water supplied by the several metropolitan water companies during the month of July, Colonel Sir Francis Bolton states that the Thames water sent out by the Chelsea, West Middlesex, Southwark, Grand Junction, and Lambeth companies contained in every case less organic matter than the previous month's samples, and even less than those collected in May, the absolute amount of this organic matter being for river water exceptionally small. Of the water taken from the Lea, that distributed by the New River Company contained slightly less, and that by the East London Company very slightly more, organic matter than any of the Thames waters. All the waters were clear on delivery.

THE POPULATION OF FRANCE.—M. Bertillon, in the course of a lecture recently delivered at the Hygienic Exhibition in Paris, stated that out of every 1000 inhabitants of Paris only 360 are natives of the city, 565 belonging to the departments of France or the colonies, and 75 being foreigners. There are in proportion as well as in actual numbers more foreigners in Paris than in most other large cities, the proportion being 75 in 1000, as against 14 per 1000 in Berlin and Trieste. The movement of the population for the past year throughout France was also very unsatisfactory, the total number of births being 922,361, or upon the average 30,000 fewer than for the last fifteen years. Moreover, out of this total, 74,118 were illegitimate, or rather more than 8 per cent. of the whole, this being the largest number of illegitimate births ever recorded. Upon the other hand, there has been a slight reduction in the number of deaths, the total for 1885 being 836,897; but even so, it will be observed that the excess of births over deaths was only 85,464.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

BINDLOSS, EDMUND, F., M.R.C.S., L.R.C.P. Lond., has been appointed Medical Officer for the West Deptford district of the Greenwich Union.

BROCKATT, A. A., L.R.C.P., M.R.C.S., has been reappointed Resident House-Physician to St. Thomas's Hospital.

CLEMOW, FRANK G., has been appointed House-Surgeon to the County Hospital, Ayr, N.B.

CROWDY, F. D., M.B.Oxon., M.R.C.S., L.S.A., has been reappointed Resident House-Physician to St. Thomas's Hospital.

EVANS, C. S., M.R.C.S., L.S.A., has been appointed Assistant House-Surgeon to St. Thomas's Hospital.

GODFREY, A. E., L.R.C.P., M.R.C.S., has been reappointed Non-Resident House-Physician to St. Thomas's Hospital.

HIRD, T. ALFRED, M.B., has been appointed Surgeon to the Coventry Provident Dispensary, vice Littlewood, F.R.C.S.Eng., resigned.

HUTTON, J. S., L.R.C.P., M.R.C.S., L.S.A., has been appointed Clinical Assistant in the Throat Department of St. Thomas's Hospital.

JONES, J. KENRICK, L.R.C.P., L.R.C.S., L.M.Ed., has been appointed Medical Officer for the Llanrhaiadr-yn-Mocknant District of the Llanfyllin Union.

KIDD, H. CAMERON, L.R.C.P., M.R.C.S., has been appointed Assistant House-Physician to St. Thomas's Hospital.

MATHESON, AUG. A., M.D., has been appointed Assistant Medical Officer to the Edinburgh Provident Dispensary, vice Bairstow, L.R.C.P., L.R.C.S., resigned.

MONTAGUE, A. J. H., L.R.C.P., M.R.C.S., L.S.A., has been reappointed Clinical Assistant in the Skin Department of St. Thomas's Hospital.

NICHOL, F. E., L.R.C.P., M.R.C.S., has been appointed House-Surgeon to St. Thomas's Hospital.

PARSONS, F. G., L.R.C.P., M.R.C.S., has been appointed Clinical Assistant in the Ear Department of St. Thomas's Hospital.

PRESTON, HENRY T., M.D. Aber., M.R.C.S., has been appointed Medical Officer for the Wolverley district of the Kidderminster Union.

RITCHIE, E. D., M.B., B.C.Cantab., M.R.C.S., L.S.A., has been appointed House-Surgeon to St. Thomas's Hospital.

ROWLANDS, JOHN W., L.R.C.P.Ed., L.F.P.S.Glas., has been appointed Medical Officer for the Anglesea No. 3 district of the Bangor and Beaumaris Union.

STAVELEY, W. H. C., L.R.C.P., M.R.C.S., has been appointed Assistant House-Surgeon to St. Thomas's Hospital.

YEOMAN, C., M.B., B.C.Cantab., M.R.C.S., L.S.A., has been appointed Resident Accoucheur to St. Thomas's Hospital.

Births, Marriages, and Deaths.

BIRTHS.

DONALD.—On the 28th ult., at Ambleside-avenue, Streatham, S.W., the wife of David Donald, M.D., L.R.C.S.E., of a daughter.

MARTYN.—On the 25th ult., at Mansfield, the wife of Ernest Martyn, M.B., of a son.

ROBERTS.—On the 28th ult., at London-street, Reading, the wife of Arthur Roberts, M.R.C.S., of a son.

TOMLINSON.—On the 29th ult., at Abbots Heyes, Chester, the wife of Surgeon-Major W. Winslow Tomlinson, Medical Staff, of a daughter.

MARRIAGES.

BURTON—BRETT.—On the 25th ult., at St. Agnes', Kennington-park, Leonard William Burton, L.R.C.P., M.R.C.S., of Burton-on-Trent, to Gertrude Alice, second daughter of Henry R. Brett, of Longridge-road, South Kensington.

FENN—JOBSON.—On the 25th ult., at Churchill, Worcestershire, Ernest Harrold Fenn, Surgeon, Grenadier Guards, to Bertha Alison, younger daughter of the late Robert Jobson, of Churchill Court, Worcestershire.

HILBERS—MATHIAS.—On the 19th ult., at St. Thomas' Church, Haverfordwest, Hermann Gerhard Hilbers, B.A.Camb., L.R.C.S., L.R.C.P.Ed., L.F.P.S.Glas., to Grace Mabel Loyd, second daughter of Henry Mathias, Esq., of Haverfordwest.

LEAK—BAGOTT.—On the 25th ult., at St. John's Church, Dudley, by the Rev. Gilbert Bradley, M.A., Vicar of St. Edmund's, Dudley, assisted by the Rev. E. H. L. Nootts, M.A., Vicar, Hector Leak, M.R.C.S., L.R.C.P., younger son of A. P. Leak, Esq., M.D., of Winsford, Cheshire, to Miriam Annie, younger daughter of Edward Bagott, Esq., of The Hawthorns, Dudley.

REYNOLDS—JACKSON.—On the 26th ult., at St. Mary Magdalene's, Munster-square, Frederick Reynolds, L.R.C.P., to Florence Edith, youngest daughter of George Jackson, Esq., of Bancroft, Hitchin, Herts.

SHEPPARD—IVES.—On the 25th ult., at St. Denys' Church, Southampton, by the Rev. T. Plunket Mooney, M.A., Vicar, Henry Anderson, Surgeon, Indian Medical Staff, youngest son of James Walter Sheppard, Esq., of The Avenue, Southampton, to Ellen Eliza (Nellie), eldest daughter of Robert Ives, Esq., M.R.C.S., L.R.C.P., &c., of Chertsey Lodge, Portswood, Southampton. No cards.

DEATHS.

CHADWICK.—On the 30th ult. (suddenly), at Buxton, Charles Chadwick, M.D., J.P., F.R.C.P., D.C.L., of Broadwater Down, Tunbridge Wells (formerly of Leeds), aged 71.

EDWARDS.—On the 26th ult., at Benarth, Hull, James Edwards, M.D., aged 76.

JEWEL.—On the 27th ult., at Sidmouth, Henry Jewel, M.D., late of Tregoney, Cornwall, in his 73rd year.

PARKER.—On the 1st ult., at Ferozepore, Punjab, India, Surgeon Hibbert Sullivan Parker, Medical Staff, F.R.C.P., F.R.C.S.Ed., M.R.C.S., aged 28.

WAKLEY.—On the 30th ult., at Heathlands-park, Longcross, Chertsey, Surrey, James Goodchild Wakley, M.D., for twenty-five years Editor of THE LANCET, youngest son of the late Thomas Wakley, M.P.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

We cannot undertake to return MSS. not used.

THE STUDENTS' NUMBER OF "THE LANCET" will be published on Saturday next, Sept. 11th. Those gentlemen holding official situations connected with medical institutions in the United Kingdom who have not yet forwarded the necessary information to our Office for publication in that number are earnestly requested to send it *without the delay of a single post.*

"PSORIASIS SOLAKE."

To the Editor of THE LANCET.

SIR,—In reply to "House Surgeon," regarding his inquiry as to the efficacy of Barff's boro-glyceride in psoriasis, let me say that, in conjunction with internal remedies and a rigid attention to a restricted diet, I have had a most gratifying result in the local application of a saturated solution of boro-glyceride and glycerine (one ounce of boro-glyceride dissolved in two ounces of warm glycerine) on one undoubted case of psoriasis (probably specific). The solution has certainly the disadvantage of being sticky; but that one objection is more than counterbalanced by its being non-poisonous, having no unpleasant odour, and its speedily allaying the oftimes intolerable irritation. The exact cause of the disease would indicate the more suitable internal remedies. I am about to give a trial to a similar solution of the boro-glyceride in a case of ulcerative (?) erosion of the cervix uteri, when I shall anxiously await the results. Should they prove satisfactory, I imagine that in all cases of stomatitis, and ulcerations generally of mucous membranes, its application would speedily be followed by a most gratifying relief of the symptoms.

I am, Sir, yours faithfully,

WM. BALFOUR FERGUSSON, M.D., M.S.

Newtown, Montgomeryshire, Aug. 30th, 1886.

To the Editor of THE LANCET.

SIR,—In answer to the letter of "House Surgeon" regarding the treatment of psoriasis, published in your issue of Aug. 28th, might I suggest to him the following ointment, recently recommended to the profession by Dr. Walter Smith of Dublin? Pyrogallic acid, forty grains; salicylic acid, twenty grains; lanolin, one ounce; adipis, one ounce. Fowler's solution, in small and regular doses, should be given for some weeks.

I am, Sir, yours faithfully,

Darwen, Aug. 28th, 1886. ROBERT REILLY, L.R.C.S.I.

SCOTTISH MEDIÆVAL MEDICINE.

THE ninth King of Scots, if we may believe the early chroniclers, rendered his reign memorable by the high honour in which he held physicians. It was in Ireland, where he spent years of exile with his father, says Buchanan, that he became familiar with medicine and its practitioners. When settled on the throne of Scotland he so inspired the courtiers with his medical tastes that the healing art, particularly surgery, became quite a patrician accomplishment, and for centuries afterwards "nemo esset in Scotia illustriore loco natus, qui vulnerum curationem non teneret." Even down to the sixteenth century surgery, especially military surgery, was a *métier* in which the Scottish aristocracy were proficient. The gallant King James IV. pursued, according to Buchanan, the traditional practice of his race and ancestry with much zeal. "Unum e vetusta gentis consuetudine hausit avide, ut vulnera scientissime tractaret: cujus rei peritia toti Scotorum Nobilitati, ut hominibus in armis assidue viventibus, fuerat priscis temporibus communis." (One thing he imbibed eagerly from the ancient custom of the Scots—to wit, the thoroughly scientific treatment of wounds: a department in which, from remote times, the whole Scottish nobility, as men living constantly under arms, had shared a common skill.)

J. T. M.—Our correspondent, we apprehend, must vote for the division of the kingdom in which he is registered as residing. The arguments for electing a veritable general practitioner in Ireland, untrammelled by any official relations to the Colleges, are very strong.

Omega.—This question is essentially a legal one.

"THE USE OF COCAINE IN CIRCUMCISION."

To the Editor of THE LANCET.

SIR,—Dr. Snow commences his last letter by stating that "the elongated prepuce is usually (if not always) a result of the neglected phimosis." I trust he will pardon my saying that I cannot admit that this assertion is sustained by facts. Having been long impressed by the amount of injury and suffering caused among children by "neglected phimosis," I have for many years carefully examined every newly-born male infant who has come under my care, and found elongated prepuces in a considerable proportion of them. Dr. Snow further suggests that dilatation should be performed "as soon as the child is found to have trouble in micturition." I would point out that before this symptom appears irreparable injury has often been done to the nervous system of the child. I have no doubt that more than "inconvenience is sometimes caused by a long prepuce without actual phimosis, as I have had occasion to operate on several boys between the ages of six and eight whose health had much deteriorated on account of this condition, and in all of whom rapid improvement followed the circumcision. Dr. Snow's application of the word "mutilation" to the removal of a small portion of useless skin seems to me somewhat grandiloquent; and I would further remind him that forcible dilatation of the prepuce is an "attempt to improve upon nature," though generally, I think, a much less successful one than circumcision. Dr. Snow makes the rather Irish remark "that every male child should have its prepuce retracted from time to time, *whether there be phimosis or not*," forgetting apparently that the existence of phimosis precludes the possibility of this proceeding until remedial measures have been adopted. I am still of opinion that the occasional retraction of an elongated prepuce, under the protection of which the subjacent glans has become unduly sensitive, and the manipulation necessary in cleansing, are apt to produce sensations not beneficial in their effect upon the child. In addition to this, it is a very difficult matter to get this measure carried out regularly and efficiently After circumcision the necessity for it practically ceases, as the ordinary operations of the daily bath are sufficient to ensure cleanliness.

I am, Sir, your obedient servant,

Inverness-terrace, Aug. 31st, 1886. GEOFFREY HETT.

THE RELATION OF TONSILLITIS TO SCARLATINA AND DIPHTHERIA.

To the Editor of THE LANCET.

SIR,—Will you kindly allow me to make one or two comments on Dr. Hingston Fox's article on the above in your issue of July 31st.

There can, I think, be no question that certain poisons circulating in the blood may and do set up acute inflammation of the tonsils, the same as they do in the various lymphatics of the body. Yet there is in some persons an unquestionable tendency to strumous enlargement of the glands generally, with or without any corresponding enlargement of the tonsils, and *vice versâ*, while both may exist together; and if we say that tonsillitis is always the result of some scarlatinal or diphtheritic poison, we must also believe that the ordinary strumous enlargement of the glands is due to the same cause. But while it is certain that the tongue in ordinary tonsillitis does not bear any resemblance to that which exists in scarlatina, and that simple quinsy is non-infectious, it cannot be doubted that tonsils of a large spongy character are a favourite soil, as it were, for germ life and growth. My own opinion is that ordinary inflammation of the tonsils is similar to that which arises in various strumous glands, and has nothing of a specific nature about it.

I am, Sir, your obedient servant,

Surbiton, Aug. 27th, 1886. F. P. ATKINSON.

ORGANISATION OF INDIARUBBER.

ACCORDING to an American contemporary, M. Professor Van Lair of Liège has announced to the Académie de Médecine the curious fact that a tube of caoutchouc placed between the two ends of a cut nerve becomes vascularised; the nerve-fibres prolong themselves into it, and finally the two ends of the nerve unite, the caoutchouc disappearing.

L. D. S.—There are many cases on record of facial paralysis which have been cured by the extraction of teeth, although there was little previous evidence to show that they were the cause of the paralysis. We should certainly recommend in this case, if the disease does not yield to other treatment, their removal; for no possible harm is done, even if the operation fails to relieve the affection.

A Constant Reader.—A book on the subject by Dr. Murrell is published by H. K. Lewis, 136, Gower-street, London.

A NEW AND IMPROVED CLAMP FOR HÆMORRHOIDS.

To the Editor of THE LANCET.

SIR,—As your correspondent, Mr. C. J. Smith, has sought to criticise my original invention for the above, I trust that, in justice to myself, you will permit me to offer a few remarks in reply thereto.

Prior to my invention I came to the conclusion that the cause of all of the very many ingenious clamps which had been constructed failing to effect sufficient parallel crushing power was the application of the force after the scissor fashion, notwithstanding that measures were adopted in many to ensure *theoretically*, but certainly not *practically*, that the jaws of the individual clamp should so approximate. I accordingly resolved to construct one to grasp the pile to be operated upon in the opposite direction, and on this principle effectual clamps could be made after various designs. But I felt that in order to obtain a clamp of the simplest and yet most powerful description it would be advisable to construct it in the shape of pincers, with the handles about four times the length of the other end, with the addition of a screw to be attached to the extremities of them (see THE LANCET, vol. ii., 1880, pp. 1 and 158; also vol. i., 1882, p. 902). Now, I maintain that your correspondent has grasped my idea of abandoning the scissor fashion, but has produced a clamp which I do not hesitate to characterise—having now had very large practical experience in the crushing operation of piles—as being most unreliable; and if he will kindly screw his clamp tightly together with a small mass, say, of brown paper, between the outer edges of the jaws, he will find that they will spring from the parallel direction, which I have not only found to be the case with the instrument, which I have seen at the maker's and figured in THE LANCET of to-day, but which fact also is well known to every intelligent mechanic—hence the now almost obsolete pattern of the hammer-spanner used. But he has figured in his sketch the lip at the extremities of the jaws and V-shaped piece particularly mentioned by me in THE LANCET, vol. i., 1882, p. 602. I also certainly do not agree with Mr. Smith that I lay too much stress upon the power actually required for the complete destruction of the tissues operated on; and I have yet to learn that his, now almost obsolete, screw hammer pattern has anything like the crushing power as compared with my clamp, apart from the most important fact that "the jaws do not approximate under pressure in a parallel direction." I confess that my clamp is somewhat heavy; but, considering that surgeons do not require to carry such an instrument in their waistcoat-pockets, it is no drawback to it, provided its performance is effectual, which I have not the slightest hesitation in asserting to be the case, having had, as I have before said, large practical experience in this branch of surgery. I am, Sir, yours faithfully,

Baron's Court, S.W., Aug. 26th, 1886. R. FITZROY BENHAM.

THE MEDICAL REGISTER.

To the Editor of THE LANCET.

SIR,—I have often seen in your columns complaints of the names of members of the profession having been struck out of the Medical Register without due inquiry having been made. The following statement will show how easily such a thing can be done, and what little trouble is really taken to ascertain the whereabouts of members before it is done. I have just received a communication stating "that attempts have been made in vain to communicate by inquiries sent to my registered address, the letters having been returned by the Dead Letter Office," &c. As physician to a large provincial hospital, and officer of health to a large combination, and receiving a score or more of letters daily, can it be possible that inquiries had been made in vain, or must not this have been the first inquiry? I have lately removed to Harrogate, and commenced practice there, and at once notified my removal to the registrar. Of this notification no notice was taken, and I heard nothing until I had sent me the strange communication above mentioned. I then wrote and asked why my notification had not received attention. The following is the reply:—"On investigation I find that your letter announcing change of address has been duly received, and the necessary correction made in the Register." No word of apology. Comment is needless. Should not it be made a *sine qua non* that before any name is struck out of the Register a *registered* letter should be sent to the registered address? I am, Sir, yours faithfully,

Harrogate, Aug. 26th, 1886. THOS. BRITTEN, M.D.

"PEMPHIGUS."

ACCORDING to the *New York Medical Journal*, M. Justin Lemaistre has recently described a contagious affection occurring among school-children in some country districts in France, which he thinks has never before been described, although the peasants have known it for some time under the name of *perléche*. It is of comparatively frequent occurrence in the country districts of Limousin. It appears at the angles of the mouth as a small abrasion, which in a short time extends along the labial commissures, forming cracks, or fissures, which give rise to pain and some hæmorrhage when the mouth is opened wide. The lesion has many of the objective characters of certain mucous patches and commissural rhagades in syphilitic children. The malady is a simple one, without constitutional disturbance, and usually lasts from fifteen to thirty days. The treatment, like the disease, is simple—merely touching the patches with sulphate of copper or alum is quite sufficient to ensure a cure.

Student.—The regulation of the General Medical Council requiring evidence of a preliminary examination in elementary mechanics came into force on Oct. 1st, 1886. It does not apply to those who passed the Preliminary Examination before that date.

A. Z.—Certainly so, if the introduction is not to a patient of the gentleman for whom our correspondent was acting.

UNQUALIFIED ASSISTANTS.

To the Editor of THE LANCET.

SIR,—In an article in THE LANCET of Aug. 28th, commenting on a correspondence in the *Sheffield Daily Telegraph* alleging the extensive employment of unqualified persons as assistants and *locum tenens*, the existence of such a practice seems to be doubted, and some information on the subject is asked for. I regret the system is not confined to Sheffield—it is pretty general throughout England; and in support of this statement permit me to record my own experience. Two years ago I acted as assistant to a medical man practising in the north of England. This gentleman, a M.D.Edin., had six assistants, in charge of as many distinct branches, and only two were qualified. Two more unqualified persons were practising in the district, and these had been assistants to the present incumbent's predecessor. The neighbouring practitioner had an assistant in charge of a branch; he also was unqualified. I now reside near Cardiff, and I know four medical men in this locality. Each has an assistant for the duties of general practice, and only one of the four is qualified. My friends report in much the same terms on other parts of England. These facts would seem to prove that at least one-half the assistants practising in the densely populated mining and manufacturing districts are unqualified. Surely, it is high time that something should be done to put a stop to this abuse. The system has nothing to recommend it. To patients it is a wrong; to qualified assistants a great hardship; to the profession in general a gigantic evil, for it has degraded the position of the medical man.

I am, Sir, yours truly,

Cardiff, Aug. 30th, 1886. C. REDDY, F.R.C.P. & S.Ed.

"TREATMENT OF STOMATITIS."

To the Editor of THE LANCET.

SIR,—No doubt the most important point in "M.B.'s" case is to endeavour to improve the state of health which gives rise to the symptom. I think, however, if he will paint over the patches three or four times a day with a solution of 120 grains of boracic acid in an ounce of glycerine he will be pleased with the result. An intimation of the effect will oblige. I am, Sir, yours faithfully,

Margravine Gardens, W., Aug. 27th, 1886. H. B. BLACKBURN.

To the Editor of THE LANCET.

SIR,—I venture to suggest to "M.R.," in the case of his patient, that he try hamamelis virginica. Frequently I have found this drug to exert a wonderfully efficacious action on the mucous surface of the mouth, stomach, and rectum. The granular effervescent hydrobromate of caffeine may ameliorate the condition of the stomach and relieve the headache. Should this treatment not prove satisfactory, holding the open mouth over the fumes of calomel heated on a piece of tin over a spirit lamp may be worth a trial.

I am, Sir, yours faithfully,

Sept. 1st, 1886. T. E. B.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Dr. Hett, London; Mr. Benham, London; Mr. Tait, Birmingham; Dr. Davies-Colley, London; Dr. Handford, Nottingham; Dr. Haviland Hall, London; Mr Lyon, London; Dr. Herman, London; Dr. Nedwill, Christchurch, N.Z.; Mr. Hamilton, Stonehouse; Dr. Weaver, Southport; Mr. Hays, Dublin; Dr. Fraser, Romford; Mr. Fulton, Edinburgh; Mr. Coates, London; Mr. Pool, Shrewsbury; Messrs. Medical Diary for the ensuing Week.

Monday, September 6.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M., and each day at the same hour.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.

ST. MARK'S HOSPITAL.—Operations, 2 P.M.; Tuesdays, same hour.

CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M.; Thursday, 2 P.M.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.

METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.

ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITALS.—Operations, 2 P.M., and each day in the week at the same hour.

Tuesday, September 7.

GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Mondays at 1.30 and Thursdays at 2 P.M.

ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.

CANCER HOSPITAL, BROMPTON.—Operations, 2.30 P.M.; Saturday, 2.30 P.M.

WESTMINSTER HOSPITAL.—Operations, 2 P.M.

WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

Wednesday, September 8.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.

MIDDLESEX HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour. Ophthalmic Operations, Tuesdays and Thursdays, 1.30 P.M.

ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Skin Department, Tuesdays and Fridays, 9.30 A.M.

ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour.

LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.

GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Saturday, 2 P.M. Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.

ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.

KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.; and on Friday, 2 P.M.; and Saturday, 1 P.M.

Thursday, September 9.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Surgical Consultations, 1.30 P.M.

CHARING-CROSS HOSPITAL.—Operations, 2 P.M.

NORTH-WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

Friday, September 10.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1.30 P.M.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

Saturday, September 11.

MIDDLESEX HOSPITAL.—Operations, 2 P.M.

SUBSCRIPTION.

POST FREE TO ANY PART OF THE UNITED KINGDOM.

One Year ..... £1 12 6 | Six Months..... £0 16 3
TO CHINA AND INDIA ..... One Year 1 16 10
TO THE CONTINENT, COLONIES, AND UNITED STATES ..... Ditto 1 14 8

Post Office Orders should be addressed to JOHN CROFT, THE LANCET Office, 423, Strand, London, and made payable at the Post Office, Charing-cross.

Notices of Births, Marriages, and Deaths are charged five shillings.

Cheques to be crossed "London and Westminster Bank."

NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post-offices letters addressed to initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on page 2, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed.

Advertisements are now received at all Messrs. W. H. Smith and Son's Railway Bookstalls throughout the United Kingdom and all other Advertising Agents.

Agent for the Advertising Department in France—J. ASTIER, 66, Rue Caumartin, Paris.

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 11, 1886.

ADDRESS TO STUDENTS.

THERE are two different conditions of mind for which the medical profession proves equally attractive. These are the scientific or philosophical and the practical. They are not incompatible with one another, and medicine has need of both. So long as there remain in man unknown organic functions, unknown processes of disease and possibilities of treatment—and the end of that era we cannot foresee,—so long will there be room for the investigator, while the man of action will always find in medical practice a test of his endurance and resource. Happily, there is in medicine nothing which need sever, but much to unite, these two great types of intellect. By basing all its procedure on the proved attainments of science, it stimulates the spirit of inquiry, at the same time that it checks extravagant speculation, by requiring the tests of experience. It follows as a natural consequence that the best practitioner will be one who, from the beginning of his career, has learned with equal zeal the methods of his art and the reasons which guide their action. It is expected of such a one—and not in vain, both by the public and his medical brethren, that while following an approved system he will observe and think for himself, and will strive in this way to enrich the common working capital of knowledge. The student in like manner must seek to be more than one-sided in his aims and studies. The mere getting of a livelihood is not everything to him; nor, on the other hand, is fame or knowledge in itself the whole object of his efforts. He will early see that in his calling, more evidently perhaps than in any other, use and reasoning, practice and theory, mingle without confusion. The course of his studies, if he diligently follow it, will impress this fact upon him, and he will be wise if he neglect no part. Let him take together now the why and wherefore along with the facts of disease and treatment, and he will best promote his own after-success. The age at which a medical course may most appropriately be entered on is a matter for consideration. Often, indeed, the student has no choice. He may have to decide at a period of life when no time is to be lost. This is certainly better than beginning too early. Many youths go straight from school to the classes of a medical college. Some of these are doubtlessly qualified by age and by education to grapple successfully with the problems to be mastered in the study of their chosen profession. Others, we have little doubt, are less favourably placed. It seems to us, indeed, that for a majority of intending students of medicine a period not earlier than from the eighteenth to the twentieth year is the most suitable at which to begin their course. There are, of course, cases in which time or means available would oppose the working of this plan, and this point of age is not so vital that we need press it as an essential.

We now come to the question of degrees and qualifications. Henceforth, it is probable that a result of the latest movement in medical legislation, the Medical Bill of 1886, will be that no student will be legally qualified to practise until he has acquired a fair proficiency in Medicine, Surgery, and Midwifery. This is so far satisfactory, and marks a distinct advance on the days of meagre single qualification. It guarantees an average intelligence on the part of practitioners which ought at least to assure public security. At the same time, we would advise all students whose opportunities allow to qualify themselves as highly as possible. At this stage of their career advantages are open to them which they may never again enjoy, and they will do well to consider that such degrees as the Doctorate in Medicine of most universities or the Fellowship in Surgery, besides attesting, as far as any qualification can, their thorough fitness to practise, can often help them to appointments which go far to assure professional distinction. With all this, however, it must be remembered that ultimate success is purchased by a man's own work, and not by any mere degree. The student is sometimes at a loss to know which medical school he should select as his *alma mater*. There are now so many hospitals and schools well qualified to afford him instruction that he can hardly fail to have his need supplied in any recognised centre of medical education in the three kingdoms. We would rather indicate what considerations are important in guiding his choice than name any one such centre. These are thoroughness in clinical and practical teaching and the possession of sufficient material for this purpose. If in any case these requirements are well met, proficiency in teaching the theory of medicine and its allied sciences may usually be counted on.

Having thus considered the various arrangements introductory to the actual beginning of professional study, we come to speak of the methods which commonly lead to success in the course itself. A point too little regarded in all schools of our day is that the true object of education is to strengthen the mind by teaching rather than merely to fill it for a time. The student has it in his power to correct the cram tendency in his own case in a considerable degree. He will do this if he can assimilate as well as learn. He must observe and practise along with his reading, and he must endeavour to do this as far as possible for every study in its own order. It is with a view to his so doing that we have laid stress upon the value of practical teaching in the medical curriculum. Again, he should not try to carry on too many subjects at once. Let him be content to work well in each department of study in its turn, and he will then find each interesting in itself, and his interest will grow as time and progress in his work reveal to him the bearings of one on the other. Moreover, he will thus be saved the anxiety and the labour, fruitless of solid advantage, which is involved in cramming hurriedly a mass of neglected subjects on the eve of some examination. Success is most assured to the steady worker, even though he may not shine in the lists of class distinctions. We do not undervalue class competitions; on the contrary, they are in several ways useful helps in education. They engender and develop interest in study; they afford opportunities for revision of which there can hardly be too many; they mark the rate of progress to the student's own perception; while, by teaching him to arrange his ideas and express them exactly, they serve as tutors for professional examinations proper, and they train him in conciseness generally. It will not be

found a good plan to select certain subjects for special attention and to neglect others. Justice to all should be the learner's maxim. Nevertheless, there are differences in the relative importance of studies. Speaking generally, we may say that during the first two years clinical observations can be only very partially understood. The junior student should not on that account, however, fail to attend the hospital. He is sure to learn something there; but by far the greater part of his time must as yet be given to the purely scientific subjects. He should strive to attain a mastery of anatomical and physiological facts, and should labour to be a good dissector. Having thus well laid a foundation in the first principles of his profession, he will follow with comparative ease their evolution in the practice of medicine and surgery, and the perversions wrought by disease will not be hard to trace. Professional examinations ought certainly to be encountered in their prescribed order. Even if he fail, the student will be better prepared for a next attempt, and he will be wise if he do his best to avoid the uncertainty, confusion, and imperfect work which would otherwise result from the grouping of many studies. As a rule he can hardly fail by taking this course, if he is reasonably steady in carrying through his work from day to day. Examiners have no interest in rejecting candidates, but the contrary. It is not their aim to spur competitors to outrun one another, but to maintain an average of proficiency which, if not low in face of the responsibility which their office entails, is not so high but that it should be reached by the great majority of careful students of fair intelligence.

There are matters connected with the plan of study to which we would draw attention. In acquiring a knowledge of medicine, the faculties of observation and memory are, on the whole, more tried and trained than any other. This is the more true because the learner must not only come to know but must become familiar with his subject. He must in many cases carry away with him not merely a description but a mental picture of his work, and he will find that the most successful method of storing the mind is to forestall forgetfulness by frequent revision. Let him revise with all he learns anew, and revise very often. It is better to study by oneself than along with others, for in such pursuits concentration is everything. Many books do not bring much advantage, at least to young students. They rather confuse by offering different presentations of their matter. One good text-book, as a rule, or at most two, should suffice for a subject. It is a mistake to transcribe notes at home; many students waste time in this way, and allow their hours for study to pass in mere penmanship. While we are engaged with this theme another point suggests itself. Is there, after all, much profit in work which is done by the midnight oil? Sometimes, we grant, such work is unavoidable. As a general rule, however, we would recommend medical students and all reading men, whoever they may be, rather to study moderately in the evening and to make use of the morning hours. It is better thus to break in on work with timely sleep than, as some do, to drive away sleep with continuous application. If the plan can be carried out, it should certainly have a trial. Students do not always see the utility of junior and senior classes in a given subject. These are, nevertheless, in some cases an almost imperative necessity. On the principle of thorough revision the more important subjects should be thus reiterated in successive sessions. Anatomy, physiology, medicine, surgery, and midwifery are each deserving of such treatment, and the student must choose from his own sense of deficiency how far he will so favour some or others. Commonly the custom of his school will also guide him in this particular.

Apart from the merely scholastic side of student life there are matters of a more personal kind, which have yet so much to do with the result of a career that we should be loth to pass them by. At this period there are many opportunities for the formation of character, as also for the confirmation, and unfortunately also the perversion, of that which is already formed. Habits of life and work which arise at this stage are not easily forgotten. The student should be careful, therefore, to pay strict heed to the disposal of his time. Regularity and punctuality will help him much in his after medical practice. Their importance to him is not the least reason why his class attendances should be prompt and continuous. He will do well to recognise what some affect to despise—namely, the fact that class lectures, even if not always brilliant, have a real value for him, partly as decided helps to study and partly as preventives of idleness. Home reading alone will not do so well as this with a teacher's exposition. The true student is a class-man, and always has been where he could. Leisure time likewise has its use to all good workers, and its appropriate method. This is sometimes forgotten. We have known hard head-workers who also laboured hard in physical exercise in the intervals of study. This is, we would say, as a rule, too much for the majority. For the student physical exercises have their place, and deservedly; but it should be the second place. The better plan for most is to make work the prime object, exercise the customary recreation. The importance of good food and fresh air may be noticed here. A liberal allowance of each is desirable. Stimulants may in most cases be omitted from the diet with advantage. As to companionship, a great deal might be said did space permit. A few hints may now suffice, for though the theory of selection in the case of friends may be well known to many, there are aged men who do not understand its application. Idle sets and vicious sets—the two are near of kin—abound in all colleges, certainly not only and not exceptionally in medical schools. The honest determination to work, and the unpretentious assertion in act of moral principle will secure the respect, if not always the approval, of any set, and will best pilot their fortunate possessor through the sometimes dangerous entrance to a successful future. The student who really has this end in view must early perceive and enter into the purpose of his profession, for here, as in all things, purpose is the very essence of character, as that is the beginning and end of success. Until he has acquired such a spirit his time will be equivalent to mere pastime in the name of work, and in the end will only bring him disappointment. The want of zeal, however, is fortunately not a common failing among medical students, and a man of energetic inclination is therefore not likely to lack either the aid of example or the spur of healthy rivalry. After all has been said and done, however, doubts and perplexities are not abolished.

The student in every such case should not hesitate to consult his professional teachers, whom he will find equally willing and able to advise him. There may be at times yet deeper necessities for which no human guide is sufficient, and in regard to such let him not hesitate to take counsel of the supreme authority, whose power he daily sees revealed in the forms and functions which it is his lot to study.

THE RECENT CHANGES IN MEDICAL EXAMINATIONS IN ENGLAND.

ALTHOUGH the advent of a uniform one-portal system of examinations has been indefinitely postponed, if not made impossible, by the passing of the recent Medical Act, yet a fairly near approach thereto is now offered to medical students by the combinations of some of the corporations for examination purposes. The Conjoint Examining Board in England of the Royal Colleges of Physicians and Surgeons has practically become the one-portal for the rising generation of English medical men, and most English students will enter the profession by passing the examinations held under the supervision of this authority. The first examination comprises (1) Elementary Anatomy and Physiology, (2) Chemistry and Chemical Physics, and (3) Materia Medica, and it was intended when the examination was instituted that it should be passed in its entirety by the end of the first year of medical study. Further experience, however, has shown that it is often necessary, in justice to the student and his teachers, that Materia Medica should be taken at a later period in the curriculum, and the examination therein can now be passed by the pupil without prejudice to further progress in either his first or second year of study. The second summer session is generally found to be the most convenient for this by those who have had no preliminary experience in pharmacy or medical practice. Elementary Anatomy and Physiology may be passed without any difficulty by a candidate of fair ability and average industry at the end of the first winter session, and Chemistry with Chemical Physics at the end of the first summer; this last subject usually requires more application than the other two, and, perhaps because its bearings on medical science and work are not so readily appreciated by the learner, failures in passing therein are very numerous. Chemistry and Materia Medica may be passed at any time after registration, even before entrance at a medical school, for any medical man or efficient teacher can give instruction therein and sign the required certificates. It must be clearly held in view, that unless these examinations in Anatomy, Physiology, and Chemistry be passed before the commencement of the second winter session, the student's further progress is practically hindered, if not absolutely barred, for six months must have elapsed after passing in these before the candidate is allowed to present himself for the second examination in Anatomy and Physiology. If, therefore, any part of the first examination (except Materia Medica) be postponed until the second winter, the candidate cannot devote that period to his further dissections and his advanced lectures in Anatomy and Physiology, and he will have to do this work in the summer months or in the third winter, when all his attention and energies ought to be given to Medicine, Surgery, and Obstetrics, and to ward work in the hospital. The necessity of passing the second examination at the termination of the second winter—viz., in the month of April—is again imperative, as a further term of two years' study is insisted on, after passing this, before a candidate is admitted to his third or final examination in Medicine, Surgery, and Midwifery. If therefore a student, with average ability and persevering industry, follows the curriculum laid down by the Conjoint Board, and passes the examinations in due order, he can obtain the double qualifications of the Royal Colleges of Physicians of London and Surgeons of England in four years from the commencement of his studies; but if he fail at any one step, even the earliest, he will be delayed and placed at a disadvantage throughout the remainder of his student work. The three examinations are held every three months, and students can pass in all the subjects of an examination taken together, or in any one subject separately. The great blot in the present regulations is the non-insistence on certificates of attendance and work by rejected candidates before they are again admitted to examination. After a student has presented himself once at a given examination and fails therein, the teacher loses all control over him, and he can offer himself over and over again for examination in the same subjects without his having been placed under any supervision in the interim, and without even his teacher's knowledge or consent. The whole system, indeed, is a little too machine-like in the precision of its details. At the Apothecaries' Hall the examinations have also been improved and brought into closer relation to those of the other bodies. Surgery is now a compulsory subject for the licence, and it must be passed before the medical part of the examination can be undergone. At the University of London two Preliminary Scientific Examinations in the year have been instituted, and after next year the Intermediate M.B. Examination will be held in January as well as in July. Other arrangements for facilitating the taking of degrees have been made by the provincial universities, such as a division into three examinations at Durham, a change in the time of holding the examinations at Manchester, the possibility of passing in the various parts of an examination separately at Cambridge, and a curtailment of the time absolutely required for taking the M.B. degree at Oxford. It is not so widely known among parents and school teachers as it should be that Elementary Mechanics—comprising the elements of statics, dynamics, and hydrostatics—is now included among the obligatory subjects which must be passed by the intending medical student before he can be registered, and if the examination in general education does not include this as well as Latin, English, and Mathematics, a separate examination therein must be passed. To meet this difficulty the Apothecaries' Society permit a candidate to take up any of the various subjects of the Preliminary Examination apart from the others, and the College of Preceptors will give a separate certificate in Mechanics.

A DEGREE FOR LONDON MEDICAL STUDENTS.

THE agitation which has been proceeding in London during the past year or two has clearly shown that the London medical student is at a decided disadvantage when compared with the students in other medical centres, should he aspire to a degree and not remain content with the diplomas of the qualifying corporations. A degree is the

more important to the practitioner in recent years from the competition induced by the holders of degrees passing into general practice instead of remaining consultants, as was formerly the more usual custom. This is a direct consequence of the large increase in men who pass out from our various universities after having observed the necessary curricula and passed the required examinations. Formerly graduates were comparatively few, and those who held qualifying diplomas were an immense majority. Of late years this disproportion has undergone a great change, and now holders of university degrees can everywhere be found in the ranks of the general practitioner, and we hail this change as one of the surest proofs of a general rise in the social and educational status of our profession during the past twenty or thirty years. It must not be forgotten, however, that, coincidently with the development of the universities as centres of medical education, the corporations have also done much for its improvement, and have so greatly altered their requirements and strengthened their examinations that they no longer hold the position to the present which they did to the former generation of medical practitioners. By the formation of a Conjoint Examining Board in England for the two Royal Colleges, a plan has been evolved from the old chaos of medical education and medical examinations; and it is a matter of much interest to review the present position of the medical student in London, and to compare his advantages and disadvantages with those elsewhere. In the first place, there can be no question that his clinical opportunities—and these are the essentials for his future practical work—are far greater in the metropolis than in any other medical centre, and that in some of the smaller provincial cities, with large medical schools, his ward work and clinical instruction must dwindle to a minimum. Against this positive gain must be set the disadvantage of his having to choose between multiple schools, with teachers of varying capacity and eminence attached to each school, whilst distance prevents any choice of classes in different schools. Undeniably, university professors, especially when extra-mural teachers have free scope as rival teachers, teach better than many in our metropolitan schools, but then they are encumbered by large classes, and can give but little personal supervision or encouragement except to a select few of their *alumni*. A direct and personal form of teaching is so much required for practical and clinical work, that we hope our smaller metropolitan schools will in time transfer the theoretical and scientific education of our students to expert teachers in three or four centres, and devote themselves and their institutions to this final work, for which they are so remarkably fitted. If such a plan could be carried out, the medical education of the London student would be almost ideally perfect, and the recent changes with regard to teaching botany and chemistry, by the practical throwing open of the certificates in these subjects, must soon bring this reform into the domain of practical expediency. But even at present, it is only just that the London student should have the proper facilities for obtaining a medical degree, and so far as the stringency and thoroughness of the present medical examinations of the Conjoint Examining Board in England are concerned, nothing more is necessary or desirable. They are quite equal to most of those instituted by the universities, and are even superior to some in the efficiency of their practical tests. There is no feasible objection, except that of the multiplication of degree-giving bodies, which can be urged against the combined colleges forming the medical faculty of a university, and having a power to grant degrees in consequence, and this objection fails when we find now all universities examining students destined for general practice, and see how valuable is the influence of a new and living institution like the Victoria University. The University of London is cosmopolitan, and can only be an examining body for the empire. It cannot control teaching, and does not pretend to do so. Nor does it regard or concern itself with the average student of our London medical schools. A Teaching University in London can only come by assimilating our medical schools, and their concentration into a medical faculty under the controlling and directing influences of the Royal Colleges must be the first step toward such a desirable course. Meanwhile the Colleges should take every measure which would pave the way towards obtaining this necessary power, for the number of graduates who are capped grows every year, and the disadvantage of not possessing a degree is ever increasing. A matriculation examination which is more real than the registrable examination of the College of Preceptors or of the Apothecaries' Hall is the first necessity, and with a suitable examination in biology in the first year of study, and perhaps a thesis for the M.D. degree, the present scheme would be put on an honours footing, leaving it as it stands for a pass, whilst those who passed in honours would be fairly and justly entitled to a degree, which would in no way lower those now in existence, but would have a distinct value on its own merits. We trust that the agitation in favour of granting medical degrees to our London students on the same conditions as in the Scotch and provincial universities will not be permitted to wane, but will become stronger and more urgent, so that all our medical candidates may be placed on an equal footing, without being obliged to forego any of the advantages of pursuing their clinical work where opportunities for it are greatest and most readily available.

MEDICAL STUDY ABROAD.

THOUGH there is probably no place in the world where a better and more thoroughly practical acquaintance with disease in all its forms may be obtained than in London, it is well that students—that is to say, more especially advanced students—should be reminded that there are medical schools and universities with abundant and admirable arrangements for teaching medicine across the English Channel, and that much advantage may frequently be gained by a session or more spent at a judiciously selected continental university. There is, too, another and a larger class of readers of THE LANCET to whom some knowledge of foreign medical matters may not come amiss at the present time; we mean the whole body of registered practitioners, who will shortly have to elect representatives to serve on the Medical Council and to help to make and enforce regulations by which the education and practice of British medical practitioners will be governed. It is surely a matter of importance to all who would give intelligent and discriminating votes at the forthcoming election to know something of "how they manage these

things" abroad, so that that which is good in foreign systems may be, if possible, assimilated, and that which is inherently bad, or which would be unsuitable to the general conditions of life in these islands, avoided.

The point on which, perhaps, we in this country differ most from our continental brethren is in the matter of preliminary education. Most continental nations require from the medical student some kind of "leaving certificate" showing that he has passed with credit through the highest class or form of a public school, or that he has had an education equivalent to what that would have implied.

In every continental country of importance, for the course for the full licence to practise a knowledge of Greek is compulsory, and generally a much more extensive knowledge of Latin, mathematics, and science than is requisite with us, even for some of the examinations belonging to a grade above the lowest. In France, for example, where the possession of the Bachelor of Letters and the Bachelor of Science (slightly modified) is compulsory on all students who desire the full privileges of practice, the requirements of the double degree may fairly be reckoned as decidedly higher than those of the London matriculation, and as covering more ground than the minimum examinations for Arts degrees at Oxford or Cambridge, though probably the stringency of the tests in the English universities is greater than in France, where nearly everything is *viva voce*. A preliminary education about equal to that indicated by an ordinary English university degree in Arts is required also in Germany, Russia, Holland, Austria, Norway, Sweden, Denmark, and Switzerland. In those countries the supply of practitioners is quite equal to the demand, for it is only in very sparsely populated districts that any complaint arises of insufficient medical aid. Indeed, the cry is just the opposite, for foreign medical journals teem, like our own, with lamentations over the increasing number of practitioners and the difficulty experienced both by the juniors and the seniors in finding enough practice. The minimum period of medical study varies considerably in different countries: being four years in France and Spain; four and a half in Germany; five in Austria, Russia, Belgium, and Portugal; six in Italy, Holland, and Denmark; seven in Norway; and ten in Sweden!

Licensing systems vary in different countries. A State examination, other than a university degree, is enforced on all in Germany, Greece, Holland, and Switzerland; also in Belgium on those who have not degrees from the two State universities. A university degree is compulsory in Austria, Denmark, and Italy, and, for the full right to practise, in France. In Norway, Portugal, Russia, Spain, and Sweden, the universities and other medical schools grant licences which constitute titles to practise. In these countries a further examination is required for the Doctorate, which in some cases, as in Norway and Russia, is of so difficult a character that few practitioners attempt it unless they aspire to professorships or important public appointments. The only country where a partial or restricted qualification is now granted is France, where the licence as *officier de santé* only gives the right to practise in the department in which it is conferred, and does not authorise the holder to perform serious surgical operations, except in the presence of a doctor. It, however, requires four years of medical study, or the same period as is necessary for the higher qualification; but the preliminary requirements are very much smaller, and the examinations are not so numerous or so stringent. At the end of the first year, the candidate for the lower grade licence is examined in physics, chemistry, natural history, osteology, and arthrology; at the end of the second year, in descriptive anatomy and physiology; at the end of the third year, in internal and external pathology. At the conclusion of the whole period he is subjected to three *examens definitifs*: the first consisting of anatomy, physiology, and practical dissection; and the second including pathology, therapeutics, materia medica, and operative medicine; the third is a clinical examination in medicine, surgery, and obstetrics. The candidates for the Doctorate have to undergo what may be considered eight examinations of a more advanced character, including, in addition to the subjects required of the *officiers de santé*, hygiene and forensic medicine. They have, besides, to defend a thesis. It may be remarked that the lower grade licence is usually found sufficient by British physicians wishing to practise in French watering-places. Leave can be obtained to undergo the final examinations only.

The German State examination is a very thorough and practical test, or rather series of tests, of the candidate's acquaintance with all branches of medical knowledge. It consists of two main examinations: The "Physicum" takes place after two years' medical study, and is conducted orally and publicly; the subjects are anatomy, physiology, chemistry, physics, botany, and zoology. The Final Examination is conducted by a commission, and before admission to it the candidate must have passed at least four years and a half in professional study, two years of which must have been subsequently to passing the "Physicum" Examination. He must have held appointments in the surgical, medical, obstetrical, and ophthalmic departments, and must have completed two labours in the presence of one of his teachers. The examination embraces anatomy, pathological anatomy and general pathology, surgery and ophthalmology, medicine, midwifery and diseases of women, and hygiene. In anatomy he has to dissect and put up a microscopic preparation; in pathology he must make a partial necropsy; in surgery, medicine, ophthalmology, and midwifery, cases have not only to be examined in presence of the examiner and reported on, but have to be taken charge of for several days under the examiner and full reports handed in daily. A labour has to be attended in the examiner's presence, and, in addition, the candidate is subjected to ordinary *viva-voce* tests, and has to perform certain operations on the dead body and on the obstetric phantom. The anatomical and physiological portion must be passed before admission to the other subjects. If the student fail in one of the latter, he may still present himself for the rest, and he may be re-examined in his "weak" subject in from six weeks' to six months' time, according to the degree of weakness. If, however, he should not pass it during the next year he must go through the whole again.

The mode of conducting medical examinations abroad differs somewhat from the plans adopted in this country, papers with several questions on the different subjects

being unusual on the Continent, where the written examination—if there should be one—generally consists of extempore essays on some one topic, often drawn by lot, so that a man has a poor chance if he happens to get a theme upon which he knows little, even though he may be pretty well prepared generally. The British system would appear to be fairer, and, to use a students' expression, less liable to "flukes." We pride ourselves rather upon the improvement which has within the last few years been introduced into our clinical examinations, in which one or more patients are actually examined and reported on by the candidate; but even that, as a test, falls far short of the German system mentioned above, of giving candidates charge of cases for several days together, making them report upon the progress and, in case of death, on the post-mortem appearances. In this country it would be difficult to find facilities for this, and impossible to make candidates attend a labour in the examiner's presence.

In the case of most of our licensing corporations the number of times a candidate may fail can, perhaps, only be properly appreciated by "chronic" students and persevering "grinders," or by parents to whom application is made for repeated fees for the same examination. This kind of thing is not tolerated in some countries: for instance, after two failures in Germany and Austria it is difficult to obtain permission for another attempt; and in Austria, if this ends in failure, the unfortunate candidate is permanently debarred from ever obtaining an Austrian qualification, and also from the "nostrification" or recognition of one obtained elsewhere.

Continental universities and medical schools generally are quite willing to allow foreign students or practitioners to attend hospital practice and lectures—in some cases without any payment, in others on payment of lecture fees. Some, too, confer M.D. degrees on English practitioners—after, of course, an examination. Arrangements, for instance, are made in Brussels by which a fully qualified English practitioner can undergo an examination (in English), and, if successful, in a week's time return with the magic letters attached to his name.

Although the Brussels M.D. is the most accessible, it is not by any means the only foreign degree that is open to Englishmen without residence. Paris, Berlin, Naples, and a number of other universities, will accept as sufficient the English medical curriculum, but the examinations imposed are generally conducted in the national language, or possibly in colloquial Latin, and the facilities afforded to a foreigner are therefore not so great as at Brussels. Austrian and Russian degrees can scarcely be obtained by English practitioners.

Licences to practise can be obtained by qualified British practitioners by examination in France, Germany, and Switzerland; and are sometimes granted without examination in Belgium, Italy, and Spain.

RECENT MEDICAL LEGISLATION AND MEDICAL STUDENTS.

IT will naturally be asked if recent medical legislation has any interest for medical students? And, if so, in what way? The essence of the change of law effected by the recent Act, as far as it concerns students immediately, is this: that henceforth, or rather after a certain day in 1887, a person shall not be registered under the Medical Acts in respect of any qualification referred to in any of these Acts, unless he has passed such qualifying examination in Medicine, Surgery, and Midwifery as in this Act mentioned. Clause 3 of the Act defines Qualifying Examinations, and what bodies shall be recognised as holding such examinations. And this is a peculiarity of the Act, that it recognises in any of the existing Universities acting singly the power to grant such a qualifying examination. Whereas, in the case of the corporations, two or more must *combine* to give such a diploma. The combination must not be one of two similar corporations, but one at least of the bodies combining must be a corporation capable of granting a diploma in Medicine, and one at least capable of granting a diploma in Surgery. In other words, the possibility of getting on the Register with a single qualification is abolished. For this purpose it is no use for a corporation to give its diploma singly. Such a diploma could not be registered by itself. This result is much boasted of by those who approve the recent Act. It is no doubt proper that any person getting on the Register should be examined in the three great branches of practice. But this end had been practically gained in all the single corporations before the Act was passed. The English College of Surgeons has long examined in medicine. The London College of Physicians has long boasted of the completeness of its examinations and the doubleness of its diploma. Even the Apothecaries' Society has elected examiners in surgery. The Scotch corporations have always examined in the three branches, and two of the three Irish corporations have done the same. Henceforth, however, the ban of disability rests on corporations acting alone, unless it be the Apothecaries' Societies, for whom it would almost seem a special clause has been introduced into this Act (Clause 5). If the larger corporations refuse to come to terms with the Apothecaries' Societies or to admit them to a scheme for combination or surgical examinations, then they can apply under Clause 5 to the Medical Council for assistant examiners, and with this assistance their examinations may become Qualifying Examinations. Conceivably, then, and probably, there will be three ways of getting on the Register—through the qualifying examination of a university, through the qualifying examination of a combination of corporations, or through the qualifying examination of a corporation assisted by the Medical Council.

Will examinations be more strict under the new law? That remains to be seen. It may be hoped, at any rate, that they will not be less so, and that they will at least be more fairly uniform, and that a qualification in one division of the kingdom will be fairly equivalent to a similar qualification in another. The reason for hoping this is that the Medical Council is made specially responsible for securing the maintenance of the standard of proficiency For this purpose it is to appoint a number of Inspectors for the Qualifying Examinations. We regard this provision of the Act with some interest, and trust that it will conduce to fair play as between one division of the kingdom and another, and between candidates and examining bodies. There is plenty of complaint of bad students. It is possible

that good examinations are too few. But with a good staff of well-selected and trained Inspectors better things may be expected.

One important feature of the new Act is the provision for electing Direct Representatives of the profession. The bearing of this on medical students and studies may not be immediately apparent. But we shall be surprised if it does not have some effect, especially if practitioners be elected who look at medical education from the standpoint of actual practice. This is the point for finding out defects in education, and the difference between hospital practice and general practice.

COLLEGIATE RESIDENCES IN LONDON.

FEW can have failed to observe the great difference in social aspect between the present generation of medical students and those which preceded it during the old apprenticeship system. Past medical students came to London with their habits and manners moulded in the country during the period (often four or five years) which they served under the tutelage and supervision of the country doctor. Idleness in the country was followed by idleness and roystering in town industry by persevering application; and both extremes were well recognised by the profession and the lay public. The medical student of those days was fairly advanced in age, and he but rarely reformed if he had been allowed to run loose and do little or no regular work or reading during his country apprenticeship. If, on the other hand, he had been placed under a judicious master, habits of regularity, punctual attendance, and steady work rarely gave way when he came to town. But since the practical abolition of apprenticeship, the pupil generally passes from his school life into his medical studentship at a bound, and without any intermediate stage. For the first two years of the curriculum he is still in many cases to every intent and purpose a schoolboy, and as such should undoubtedly be more carefully looked after and guarded from evil influences than is either possible or useful in the case of the older student. To meet this many methods of living for students in London have been suggested. The question is of the utmost importance, for the same difficulties have arisen in regard to the theological and legal as with the medical students. The former generation almost always resided in lodgings chosen by themselves and left to themselves, if we except a few who had friends in London, or who boarded and lodged with members of the staff of the medical school or hospital which they attended. Collegiate residences were practically unknown until arrangements were made by the authorities at the foundation of King's and University Colleges for residential students. But with the modification in medical education, necessitating a residence in London during a most impressionable period of life, parents have become much more desirous of supervision of their sons, and the isolated life and absence of restraint have been freely held up of late years as the cause of and an excuse for laxiness and other vices. The collegiate system and private care of pupils are in increasing demand, and for these residences—public and private—the registers of lodging-houses, under a quasi-supervision, which are kept by the authorities of many schools, are but a poor substitute. The collegiate system must spread from the four schools which have partially adopted it—viz., St. Mary's, St. Bartholomew's, King's and University Colleges—to the others, and Middlesex is now following in their path. But even in these the number of rooms is very disproportionate to the number of students, although, perhaps, not to the present demand. But this demand will grow larger and become more imperative now that attention has been so publicly and pointedly called to the question. At the older universities residence under supervision is absolute, and the other centres of medical education will be compelled to adopt some similar system. The provincial, Scotch, and Irish schools are in the same position as those of London, and must follow on the same lines.

THE CHOICE OF A TEXT-BOOK.

THE question which the student is always asking, and naturally, is what book will best serve his purpose in preparing for certain examinations. The answer to this question is one which becomes every year more difficult. The number of medical text-books of a high class is now very great; therefore to select a few from amongst them may seem invidious. At the same time a list, which by no means pretends to be exhaustive, can be drawn up that may prove of value as a guide to the student in his choice. As representing all the various examining bodies, we may take for this purpose the Examining Board for England (Royal College of Physicians and Royal College of Surgeons) and the University of London.

THE EXAMINING BOARD FOR ENGLAND.

For the *First* Examination of this Board the student will be required to have gained a fair knowledge of Elementary Anatomy and Physiology, of Chemistry, Materia Medica, and Pharmacy; and if he be diligent he should be able to pass both parts of the examination by the close of his first year. In *Anatomy*, he may have recourse to GRAY'S Text-book, and to the works on *Osteology* by WARD, HOLDEN, and NORTON. In *Physiology*, the Elementary Text-book of HUXLEY might well be mastered first. In *Chemistry*, ROSCOE'S Elementary book and ATTFIELD'S work. In *Chemical Physics*, FOWNES' Inorganic Chemistry edited by WATTS, or BALFOUR STEWART'S Elementary Physics. In *Materia Medica*, the works of MITCHELL BRUCE, ROBERTS, GARROD, and BRUNTON or OWEN'S Elements.

For the *Second* Examination (corresponding to the Primary Membership at the College of Surgeons), the subject of *Anatomy* may be well studied in GRAY'S Anatomy, ELLIS'S Demonstrations, or HEATH'S Practical Anatomy. The anatomical plates of ELLIS and those of GODLEE are very useful in supplementing practical work, or the handier volume of MASSE. In *Physiology*, the books most to be recommended are KIRKES' Handbook, G. YEO'S Text-book, and H. POWER'S Elements; and *Histology*, apart from the sections devoted to it in the works of GRAY and KIRKES, may be read in KLEIN'S Elements.

For the *Third* or Final Examination, in the subjects of *Surgery* and *Surgical Anatomy*, there are the Text-books of BRYANT, HOLMES, GANT, and ERICHSEN'S work, ably edited by MARCUS BECK, the System of Surgery edited by TREVES, the Practical Handbooks of BERKELEY HILL, CHRISTOPHER HEATH, PEARCE GOULD, and TREVES'S Applied Surgical

Anatomy. For *Surgical Pathology* PEPPER or BILLROTH may be recommended. In *Diseases of the Eye*, LAWSON or NETTLESHIP. In *Medicine*, the Text-books of ROBERTS and BRISTOWE, preceded by the smaller works of CARTER or CHARTERIS. *Clinical Medicine:* FENWICK, FINLAYSON, or GRAHAM BROWN. *Pathology:* GREEN, COATS, and ZIEGLER (MACALISTER'S translation), and WOODHEAD'S practical work. *Therapeutics:* BARTHOLOW, RINGER, NAPHEYS, and FARQUHARSON. *Medical Jurisprudence:* the Text-books of GUY and TAYLOR. *Public Health:* WILSON. *Midwifery:* PLAYFAIR or GALABIN.

COLLEGE OF SURGEONS (FELLOWSHIP).

In addition to the anatomical and physiological works above mentioned, there may be read for the Primary F.R.C.S. (especially its histological and embryological sections)—QUAIN'S Anatomy, FOSTER'S Text-book of Physiology, LANDOIS' work edited by STIRLING, and GEGENBAUR'S Comparative Anatomy. Professor FLOWER'S Osteology of the Mammalia might also be read. For the Pass Examination, ERICHSEN'S work may be supplemented by chapters in the System of Surgery edited by HOLMES and HULKE. In *Operative and Practical Surgery*, there are works by STIMSON, FERGUSSON, and S. SMITH and HEATH'S ATLAS. PAGET'S or BILLROTH'S Surgical Pathology and ZIEGLER'S Pathology may be profitably read in connexion with works mentioned under the Conjoint Examination.

UNIVERSITY OF LONDON EXAMINATIONS.

For the Intermediate M.B. Examination of the University of London, the subject of *Organic Chemistry* may be studied in the Text-books of WILLIAMSON and of FOWNES. *Materia Medica*, besides the books above mentioned, is more fully treated in the works of BRUNTON, PHILLIPS, BARTHOLOW, and H. G. WOOD. *Physiology* as for the Primary F.R.C.S., with perhaps the addition of such books as that of POWER and HARRIS for practical work and of SCHAEFER for practical histology. The anatomical text-books are those recommended above. For the M.B. Examination, the subject of *Medicine* may profitably be further studied in NIEMEYER'S Text-book, in the exhaustive and scientific treatise of the late Dr. HILTON FAGGE, in that of AUSTIN FLINT, in REYNOLDS'S System of Medicine, and in TROUSSEAU'S Lectures. Special monographs (see M.D. Exam.) may also be consulted. *Pathology*, which should be worked at practically, may be studied in GREEN'S, COATS', or ZIEGLER'S Text-books, and also in the works of WILKS and MOXON, and in those of CORNIL and RANVIER; *Midwifery*, in the writings of PLAYFAIR, GALABIN, LEISHMAN, LUSK, and BARNES; *Gynæcology*, in those of GALABIN, LOMBE ATTHILL, EDIS, M. JONES, and BARNES; *Dermatology*, in the Text-books of TILBURY FOX, LIVEING, DUHRING, and M. MORRIS; *Medical Electricity*, in DE WATTEVILLE or POORE; *Medical Ophthalmoscopy*, in GOWERS' Handbook. For the M.D. Examination the candidate will do well to extend his reading to the better-known monographs, such as MURCHISON on *Continued Fevers* and on Diseases of the Liver; ROSS, CHARCOT, and WILKS on Diseases of the Nervous System; BALFOUR, BYROM BRAMWELL, and WALSHE on Diseases of the Heart; POWELL and WALSHE on Diseases of the Lungs; RALFE, W. ROBERTS, and DICKINSON on Diseases of the Kidney.

In the foregoing lists we have mostly indicated more than one work upon a subject; for it is, of course, impossible to make a single selection from among so large a number of excellent works. A certain amount of choice must be left to the student himself, who will do well to be guided in this respect by the opinion of his teacher in the particular subject.

ARMY, NAVY, AND INDIAN MEDICAL SERVICES.

THESE three branches of the public medical service maintain their popularity with the junior members of the profession, if we may judge by the numbers of candidates who present themselves at the competitive examinations held twice a year. If we mistake not, they were in the proportion of two candidates for each vacancy at the examination in August. These services certainly offer some very appreciable advantages, either as a career for life or as a temporary occupation for a few years. After a successful competition at the examination in London, the "surgeon on probation" for the Army and Indian Service is sent to Netley to undergo a course of special training for a period of four months, during which he receives pay at the rate of 8*s.* a day, with free quarters. We consider this course, which includes Military Surgery, Military Medicine, Pathology, and Hygiene, to be of great value. On its conclusion, the "surgeon on probation" is gazetted to the medical staff or Indian Medical Service as Surgeon, with the relative rank of Captain. In the Navy, the successful candidate is sent at once to Haslar and gazetted as Surgeon. He undergoes there a certain amount of special instruction, but we believe it is not at all to be compared with that given at Netley. The advantages of the public service are that the medical officer starts at once on his career with a fair amount of income, which is totally independent of the caprice or goodwill of his patients; that he goes on with the certainty of an increase of pay and improved position after a certain number of years, and, if he continue in the service, with a retiring pension after twenty years proportionate to the length of time he has served and the rank he has attained; or, if he wish to quit it sooner, he can do so at any time, receiving a gratuity after ten, fifteen, or eighteen years. The drawbacks to the service undoubtedly are the amount of foreign service and consequent absence from England, which must fall to the lot of all officers, and the unhealthy climates in which they may be called upon to serve; but this also has its attractions for those who care to be in foreign lands, and who are desirous of investigating the various forms of tropical disease, or who have a bias for the study of natural history. We cannot but think that the public services, as at present organised, offer a career which is well deserving the consideration of medical students who have not any special local ties or exceptional prospects of success in civil life.

PUBLIC HEALTH QUALIFICATIONS.

MR. EDWIN COONEY, hon. secretary to the Association of Medical Practitioners qualified in Sanitary Science, has favoured us with the following information.

As Public Health Qualifications have now received State recognition and are so much to the fore, perhaps a few statistics or particulars referring to such may not be out of place. By referring to the subjoined table, it will be ob-

served that Trinity College, Dublin, commenced granting such qualifications as early as 1871, and since then the aggregate annual number has increased, with a notable falling off from 1878 to 1880. For the present year, it is not certain what the number will be, as most of the qualifications are given from September to December. Up to the present time 233 qualifications have been given, but as nine men hold two qualifications each, there are about 224 qualified. Edinburgh has given forty-five degrees, but as eight have proceeded from B.Sc. to D.Sc., thirty-seven only are noted:—

The distribution of those holding these qualifications are as follows: London, 52; Provinces, 90; Scotland, 16; Ireland, 16; Indian Medical Service, 22 (Bengal 15, Bombay 3, Madras 3); Army Medical Department, 11; Australia, 5; India, 3; France, 1; New Zealand, 1; Canada, 1; West Indies, 1; not known, 5.

Twelve out of fifteen bodies are granting Public Health qualifications. Of these, four are called Certificates in Public Health (Univs. Oxf. and Lond., Roy. Coll. Phys. Edin., F.P.S. Glas.); three are called Sanitary Science Certificates (Univs. Camb. and Durh., K.Q.C.P. Irel.); one is called B.Sc. or D.Sc. in Public Health (Univ. Edin.); one, Qualification in Public Health (Univ. Glas.); one, Diploma in State Medicine (Trin. Coll. Dub.); one, Diploma in Sanitary Science (Roy. Univ. Irel.); and one, Certificate in Hygiene (Roy. Coll. Phys. Lond.). It is not quite certain what the whole of the respective holders of these certificates, degrees, diplomas, and qualifications in Hygiene, Public Health, Sanitary Science, and State Medicine are to be called now that Public Health diplomas are registrable under Clause 21 of the Medical Act, 1886. The Irish Universities style their men "Diplomates," and the Edinburgh University "Bachelor" or "Doctor."

We gladly give publicity in the Students' Number to this interesting statement, which shows very clearly the increasing number of medical men who are certified by different educational bodies to have a special knowledge of Sanitary Science. The subject is one of much importance, because it may be anticipated that local authorities will regard with favour those who can claim to possess such qualifications. As yet the teaching of Hygiene and Public Health has not been regarded as of sufficient importance to necessitate special arrangements being made at all medical schools for a thorough course of instruction in this branch of professional knowledge. In another part of this Number will be found the tabular list of the classes, lecturers, &c., at the different medical schools, and students who may anticipate that in the future they may be called upon to hold Public Health appointments will necessarily have regard, in their selection of a school, to the arrangements which are made in each for the teaching of this subject.

THE ADVANTAGES OF THE STUDY OF PSYCHOLOGY.

IT is strange, but true, that although many of our examining bodies would never dream of permitting a student to practise medicine, surgery, or obstetrics unless he had given ample proofs of his qualification, yet he is allowed to incarcerate Her Majesty's subjects in an asylum without any proper evidence having been adduced that he possesses the requisite knowledge of insanity or of the laws which bear upon this most important branch of medicine. But few students recognise the advantages of a knowledge of lunacy. It may of course be said that only a few can attain to the envied post of superintendent of an asylum, that those who already have reached this summit of ambition are picked men, selected out of a large number of applicants by a severe system of competition; that, in fact, the race is to the swift, the battle to the strong. But it is not to this class of aspirants that we wish to address our remarks. It is rather to the general practitioner, he whose industry is rightly said to form the backbone of the profession, and to whom in the first instance the family fly for advice when one of their relatives becomes afflicted with unsoundness of mind. Such men, we regret to say, when they leave the schools, may have never seen a lunatic: they may have never been instructed in the simple act of filling up a certificate, and in consequence a large percentage of these certificates are returned as invalid. Then, again, with regard to the dangers incurred by those who ignorantly fill up these certificates. The records of the daily papers sufficiently prove that the pocket of the certifier may be seriously affected should he omit some apparently trivial and red-tape matter of detail, which is probably mentioned in the marginal notes. A certificate has been found invalid in a court of justice simply because the number of the house in which the patient resided was omitted from the "form." Some practitioners wisely abstain from signing

certificates at all. Of late some action has been taken in the matter, and the Royal College of Physicians of London, the London University, the Society of Apothecaries, the Royal College of Physicians of Edinburgh, and, we believe, other qualifying bodies, have instituted an examination in psychological medicine; at most of our medical schools there now exists a course of lectures on insanity. And we have reason to believe that so far the work has been satisfactorily done. But we wish more especially to point out to students that should they require additional proof of their knowledge in mental therapeutics, whether with the object of seeking those coveted appointments to which we have already alluded, or simply with a view to protect themselves from litigation, now is the time to prove that they are in earnest. Quite recently the Medico-Psychological Association has established an examination for a certificate in psychological medicine, information regarding which can be obtained from any of the lecturers on insanity at our metropolitan schools. The details concerning the certificate are also given in full in the *Journal of Mental Science* for July. Briefly, the candidates must be twenty-five years of age, must have resided as clinical clerk or assistant medical officer in an asylum for at least three months, and must, of course, be duly registered. The examination is chiefly practical, no knowledge of mental philosophy or of microscopical anatomy being required. The idea has doubtless been taken from the success which has attended the establishment of a certificate in hygiene at Cambridge and at the College of Physicians. We have every reason to believe that the electing bodies for appointments of medical officers of health lay great stress upon the fact that a candidate has a special knowledge of the work he is about to undertake. And in the present day, when the public interest themselves far more about medical matters than was the case in the time of our grandfathers, it is reasonable to conclude that those who have availed themselves of the opportunities which now offer will have surely a better chance of attaining to the desired post of director of an asylum, and also will be more likely to secure the confidence of the relatives of a lunatic, if they can prove that they possess a knowledge of mental disease. We are glad to find that the tests for the certificate we have mentioned include the clinical examination of insane patients, and also that candidates are required to properly fill up medical certificates.

DENTAL EDUCATION.

DENTAL SURGERY has been attracting considerable attention of late years, and its practice rapidly gaining favour. The odium with which it was regarded on account of the large number of, to say the least, uneducated men who filled the ranks, has to a great extent been removed, and will entirely disappear now that no one will be allowed to call themselves Dental Surgeon without a diploma. For a student with a mechanical turn, the manipulations, the constant demands for the display of ingenuity, and the endless variations of the operations in dental surgery must have a great charm. One great advantage is that a man gets into practice earlier than in most other branches of the medical profession. In these days when long and elaborate operations are becoming more and more the practice, the capability of considerable endurance, both mental and physical, is required by the dentist.

In order to be legally entitled to practise it is not necessary that the student should have any diploma but that in Dental Surgery; but we would strongly urge anyone who hopes to attain a high rank in his profession, and who values his future social position, to add a medical qualification; and he cannot do better than take the L.R.C.P. and M.R.C.S. under the Conjoint Scheme, and we will briefly sketch how this may be effected.

The regulations for the diploma in Dental Surgery of th College of Surgeons of England, apart from those included in the general hospital course, are that the candidate should have been engaged in the acquirement of professional knowledge during four years; have attended at a recognised school two courses of lectures upon each of the following subjects—viz., Dental Anatomy and Physiology (Human and Comparative) Dental Surgery, Dental Mechanics, and one course of lectures on Metallurgy by lecturers recognised by the College; have been engaged, during a period of not less than three years, in acquiring a practical familiarity with the details of Mechanical Dentistry, under the instruction of a competent practitioner, except in the cases of qualified surgeons, when not less than two years instead of three will be sufficient; and, lastly, of having attended at a recognised dental hospital, or in the dental department of a recognised general hospital, the practice of Dental Surgery during the period of two years.

If the student have already passed the matriculation of the University of London or other examination allowed by the Medical Council, he must register as a *dental* student. The next step is to become articled to a registered dental surgeon, and upon the training received during this period will largely depend his future success in that important branch—Dental Mechanics, &c. It is the unanimous opinion that the three years prescribed by the College of Surgeons is not a day too long to enable the student to master its details. If a preliminary examination has not been passed, the student should nevertheless take up his articles, and present himself for such examination during the first or second year of his pupilage; for, by the regulations of the Medical Council, the three years' instruction in Mechanical Dentistry, or any part of them, may be taken by the dental student either before or after his registration; but no such year of mechanical instruction shall be counted as one of the four years of professional study unless taken after registration. Immediately he has passed the preliminary he should register as a dental student.

During his pupilage the student should familiarise himself with most of the subjects required for the First Professional Examination—Chemistry, Chemical Physics, Materia Medica, Elementary Anatomy, and Physiology, and more especially Dental subjects,—so that when he joins the hospitals his work may be more easy for him, and also that he may not during his apprenticeship "forget how to learn." This part of his career finished, the student should join a general hospital and register as a *medical student*. A word about the choice of a general hospital. It is of undoubted advantage to enter a school where there are several other men taking the same course; it is also convenient that the general and dental hospitals should be near together.

For the course of instruction to be pursued at the general hospital reference should be made to another portion of this journal. The student should join the dental hospital after having passed the Second Professional Examination, which should, supposing he joined in October, be at the commencement of the second summer session. During this session, one course of lectures on Dental Surgery and Pathology and one on Dental Anatomy and Physiology and Dental Hospital Practice must be attended. During the third winter, one course on Dental Mechanics and Dental Hospital Practice. In the third summer, one course on Dental Surgery and Pathology, and one on Dental Anatomy and Physiology and Dental Hospital Practice. And in the fourth winter, one course on Dental Mechanics, and one on Metallurgy and Dental Hospital Practice.

SESSION 1886-87.

GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION OF THE UNITED KINGDOM.

Registration of Medical Students.—The following are the General Medical Council's Regulations in reference to the registration of students in medicine:—

Every medical student shall be registered in the manner prescribed by the General Medical Council. No medical student shall be registered until he has passed a preliminary examination as required by the General Medical Council,[1] and has produced evidence that he has commenced medical study. The commencement of the course of professional study recognised by any of the qualifying bodies shall not be reckoned as dating earlier than fifteen days before the date of registration. The registration of medical students shall be placed under the charge of the branch registrars. Each of the branch registrars shall keep a register of medical students according to a prescribed form, and shall enter therein the name, the preliminary examination and date thereof, the date of registration, and the place and date of commencement of medical study, as certified by a master or a teacher, or an official in a medical school or hospital. Every person desirous of being registered as a medical student shall apply to the branch registrar of the division of the United Kingdom in which he is residing; and shall produce or forward to the branch registrar a certificate of his having passed a preliminary examination as required by the General Medical Council, and *evidence that he has commenced medical study*. The branch registrar shall enter the applicant's name and other particulars in the Students' Register, and shall give him a certificate of such registration. Each of the branch registrars shall supply to the several qualifying bodies, medical schools, and hospitals, in that part of the United Kingdom of which he is registrar, a sufficient number of blank forms of application for the registration of medical students. The several Branch Councils—and in England the Executive Committee, if its meeting be more convenient and the case be urgent—have power to admit special exceptions to the foregoing regulations as to registration, for reasons which shall appear to them satisfactory. A copy of the Register of Medical Students, prepared by each of the branch registrars, shall be transmitted on or before December 31st, in each year, to the registrar of the General Council, who shall, as soon as possible thereafter, prepare and print, under the direction of the Executive Committee, an alphabetical list of all students registered in the preceding year, and supply copies of such authorised list to each of the bodies enumerated in Schedule A to the Medical Act (1858), and through the branch registrars to the several medical schools and hospitals. The several qualifying bodies are recommended not to admit to the final examination for a qualification under the Medical Acts any candidate (not exempted from registration) whose name has not been entered in the Medical Students' Register at least forty-five months previously. In the case of candidates from other than schools of the United Kingdom, the Branch Councils—and in England the Executive Committee, if its meeting be more convenient and the case be urgent—have power to admit exceptions to this recommendation.

Pursuant to resolutions passed by the General Medical Council at its meetings on October 16th, 1884, and May 14th, 1885, the Regulations for Preliminary General Education, which take effect from October 1st, 1885, are as follows:—

On and after October 1st, 1885, no person shall be allowed to be registered as a medical student unless he shall have previously passed (at one or more examinations) a preliminary examination in the subjects of general education as specified in the following list:—1. English Language, including Grammar and Composition. 2. Latin, including Grammar, Translation from specified authors, and Translation of easy passages not taken from such authors. 3. Elements of Mathematics, comprising (*a*) Arithmetic, including Vulgar and Decimal Fractions; (*b*) Algebra, including Simple Equations; (*c*) Geometry, including the first book of Euclid, with easy questions on the subject matter of the same. 4. Elementary Mechanics of Solids and Fluids, comprising the Elements of Statics, Dynamics, and Hydrostatics. 5. One of the following optional subjects: (*a*) Greek, (*b*) French, (*c*) German, (*d*) Italian, (*e*) any other Modern Language, (*f*) Logic, (*g*) Botany, (*h*) Zoology, (*i*) Elementary Chemistry.[2]

W. J. C. Miller, B.A., Registrar of the General Council and of the Branch Council for England, 299, Oxford-street, London, W. James Robertson, Registrar of the Branch Council for Scotland, 4, Lindsay-place, George IV. Bridge, Edinburgh. R. L. Heard, M.D., Registrar of the Branch Council for Ireland, 35, Dawson-street, Dublin.

REGULATIONS OF THE MEDICAL EXAMINING BOARDS IN THE UNITED KINGDOM.

UNIVERSITY OF OXFORD.

A student may take the degree of Bachelor of Medicine after he has been admitted to the degree of Bachelor of Arts, provided that he has passed the examinations prescribed for the B.M. degree.

For the B.A. degree a student must have kept the statutable residence—viz., twelve terms (three years) from his matriculation; and after passing Responsions and the First Public Examination must take honours in one of the seven Honour Schools, or pass the examination appointed for those who do not seek honours. The limit of time for honours in the Second Public Examination is sixteen terms, but if the candidate has taken honours in one of the schools the time is extended to twenty terms.

There are two examinations for the B.M. degree. The subjects of the First Examination are:—(1) Organic Chemistry in its special relation to Physiology and Medicine, (2) Human Anatomy, and (3) Human Physiology. Candidates who have taken a first- or second-class in Organic Chemistry or Animal Physiology are exempted from the corresponding part of the M.B. Examination. The subjects of the Second Examination are:—(1) Medicine, (2) Surgery, (3) Midwifery, (4) Pathology, (5) Forensic Medicine, and (6) Materia Medica and Pharmacy.

The subjects of Organic Chemistry and Materia Medica and Pharmacy may be taken alone, and the other subjects passed at a future examination.

The examinations are held yearly in the Trinity Term, the latter part of the Summer Term.

Any person who has taken the B.M. degree may supplicate

[1] Exception may be made in the case of a student from any Indian, Colonial, or Foreign University or College, who shall have passed the matriculation or other equivalent examination of his University or College, provided such examination fairly represents a standard of general education equivalent to that required in this country.

[2] In the case of students in Universities with a prolonged curriculum, where the examination in Mechanics required for their degree is taken at a more advanced period of study than before commencing medical education, registration can be effected only on having passed the examination in Mechanics, but their registration may be then antedated to the period at which the Preliminary was passed.

for the degree of Doctor of Medicine, provided that he has entered on the thirty-ninth term from his matriculation, and that his name has been on the books of some College or Hall, or on the Register of Non-collegiate Students, for twenty-six terms, and that he has written a dissertation, which he shall deliver to the Regius Professor of Medicine.

Every person admitted to the degree of Bachelor of Medicine shall, *ipso facto*, be admitted to the degree of Bachelor of Surgery. He can supplicate for the degree of Master of Surgery after the twenty-sixth term from his matriculation, provided his name has been on the books twenty-six terms, and he has passed an examination in Surgery, Surgical Anatomy, and Surgical Operations, which will be held in Trinity Term, after the Second Examination for the B.M. degree.

More detailed information may be obtained from the University Calendar: the University Statutes, 1886; from the Student's Handbook to the University; from the Regius Professor of Medicine; from the Professors in the several departments; and from the Sub-Librarian in the Radcliffe Library at the Museum.

UNIVERSITY OF CAMBRIDGE.

The student must enter at one of the Colleges, or as a non-collegiate student, and keep terms for three years by residence in the University. He must pass the Previous Examination in Classics and Mathematics, which may, and should if possible, be done immediately on coming into residence in October, or, which is best, obtain exemption through the Oxford and Cambridge Schools Examination Board or the Local Examinations, before commencing residence. He may then devote himself to medical study in the University, attending the hospital and the medical lectures, dissecting, &c. Or he may proceed to take a degree in Arts, either continuing mathematical and classical study and passing the ordinary examinations for B.A., or going out in one of the Honour Triposes. The Natural Sciences Tripos is the most appropriate, as the subjects are the same as those for the First and Second M.B. Examinations.

For the degree of *Bachelor of Medicine* five years of medical study are required, except in the case of medical students who have graduated with honours as Bachelors of Arts, four years only being then required, though it is rarely sufficient. This time may be spent in Cambridge or elsewhere. The first three or four years are usually spent in Cambridge, the student remaining in the University till he has passed (say) the examination for the Natural Sciences Tripos and the first and second examinations for M.B. Cambridge being now a complete School of Medicine, all the requisite lectures and hospital practice may be attended here, and many students remain to attend lectures and hospital practice until they have passed the first part of the third examination for M.B. The supply of subjects for Dissection and Practical Surgery is unusually abundant.

There are three examinations for M.B. The *first* in Chemistry and other branches of Physics, and in Elementary Biology. These may be taken together or separately. The *second* in Human Anatomy and Physiology, and in Pharmacy and Pharmaceutical Chemistry. These may be taken together or separately. The *third* may be also taken in two parts—viz., (1) Principles of Surgery (with Clinical Surgery) and Midwifery and Diseases of Women, and (2) Pathology, Principles and Practice of Medicine, Elements of Hygiene, and Medical Jurisprudence. The examinations are partly in writing, partly oral, and partly practical, in the hospital, in the dissecting-room, and in the laboratories.

Previously to the first examination, lectures must have been attended on Chemistry (with manipulations). Previously to the second examination, the student must have attended Lectures on Human Anatomy, Pharmacy and Pharmaceutical Chemistry, and Physiology, have dissected for six months, and attended Hospital Practice six months. Previously to the first part of the third examination, he must have attended Lectures on Pathological Anatomy, the Principles of Surgery and Midwifery, the Surgical Practice of a Hospital with Clinical Lectures for a year, ten cases of Midwifery, and produce a certificate of proficiency in Vaccination. Previously to the second part of the third examination, he must have attended Lectures on the Principles and Practice of Physic, the Physiological Action and Therapeutic Uses of Drugs, and Medical Jurisprudence; also the Medical Practice of a Hospital with Clinical Lectures for three years, and have been Clinical Clerk for six months.

The degree of *Doctor in Medicine* may be taken three years after that of M.B. An Act has to be kept, with *viva-voce* examination; and an extempore essay has to be written on some subject relating to Physiology, Pathology, the Practice of Medicine, or State Medicine.

The candidate for the examination for the degree of *Bachelor of Surgery* (B.C.) is required to have passed the *first* and *second* examinations, and the first part of the *third* examination for M.B.; to have attended the Surgical Practice of a Hospital for two years, have acted as House-Surgeon or Dresser for six months, and have gone through a course of instruction in Practical Surgery. The subjects of the examination are Surgical Operations and the application of Surgical Apparatus; the Examination of Surgical Patients is now included in the first part of the *third* examination for M.B. Before *admission* to the degree he must also have passed the *second* part of the third examination for M.B.

For the degree of *Master in Surgery* (*M.C.*) the candidate must have passed all the examinations for B.C. two years. He is required to pass an examination in Surgical Anatomy and Surgical Operations, Pathology, and the Principles and Practice of Surgery.

An abstract of the Regulations and Schedules of the range of the examinations in Chemistry, Physics, Biology, and Pharmacy may be obtained by sending a stamped directed envelope to the Assistant-Registrar, Cambridge. Full information is contained in the *Cambridge University Calendar*.

UNIVERSITY OF LONDON.

The *Matriculation Examinations* take place on the second Monday in January and the third Monday in June. Candidates must be above sixteen years of age. The fee for the examination is £2. Provincial examinations are appointed by the Senate from time to time at specified centres. Several scholarships, exhibitions and prizes are associated with these examinations.

The *Preliminary Scientific (M.B.) Examination* takes place twice in each year, commencing on the third Monday in July and the third Monday in January.[3] No candidate will be admitted to this examination until he shall have passed the Matriculation Examination, nor unless he have given notice of his intention to the registrar at least one calendar month before the commencement of the examination. Fee for this examination, £5.

Candidates are examined on the following subjects:—Inorganic Chemistry, Experimental Physics, and General Biology. Candidates for Honours, who have entered for the whole examination, may also be examined in Botany and Vegetable Physiology, and Zoology, unless they have previously obtained an exhibition in any one of the subjects of this examination at the Intermediate Examination in Science, in which case they shall not be admissible to the examination for Honours in that subject.

Bachelor of Medicine.—Every candidate for the degree of Bachelor of Medicine will be required—1. To have passed the Matriculation Examination in this University. 2. To have passed the Preliminary Scientific Examination. 3. To have been engaged in his professional studies during four years subsequently to passing the Preliminary Scientific Examination[4] at one or more of the medical institutions or schools recognised by this University, one year at least of the four to have been spent in one or more of the recognised institutions or schools in the United Kingdom. 4. To pass two examinations in Medicine.

Intermediate Examination.—The Intermediate Examination in Medicine takes place twice in each year, once for Pass and Honours, commencing on the second Monday in July, and once for Pass candidates only, commencing on the third Monday in January, the January examination being held for the first time in 1888. No candidate shall

[3] Candidates for the degree of M.B. are required after Jan. 1st, 1885, by the Senate to pass the Preliminary Scientific Examination before commencing their regular medical studies, and are recommended to devote a preliminary year to preparation for it, according to the following programme:—Winter Session: Experimental Physics, Chemistry (especially Inorganic), Zoology. Summer Session: Practical Chemistry (Inorganic), Botany.

[4] Candidates who passed the Matriculation Examination in January, 1885, or previously, will be allowed to date the commencement of their professional studies, as heretofore, from that examination.

be admitted to this examination unless he have passed the Preliminary Scientific Examination at least two years previously, and have produced certificates to the following effect:—1. Of having completed his nineteenth year. 2. Of having, subsequently to having passed the Matriculation Examination, been a student during two years at one or more of the medical institutions or schools recognised by this University, and of having attended a course of lectures on each of three of the subjects in the following list: Descriptive and Surgical Anatomy, Histology and Physiology, Pathological Anatomy, Materia Medica and Pharmacy, General Pathology, General Therapeutics, Forensic Medicine, Hygiene, Obstetric Medicine and Diseases peculiar to Women and Infants, Surgery, Medicine. 3. Of having, subsequently to having passed the Preliminary Scientific Examination, dissected during two winter sessions. 4. Of having, subsequently to having passed the Preliminary Scientific Examination, attended a course of Practical Chemistry, comprehending practical exercises in conducting the more important processes of General and Pharmaceutical Chemistry, in applying tests for discovering the adulteration of articles of the Materia Medica and the presence and nature of poisons, and in the examination of mineral waters, animal secretions, urinary deposits, calculi, &c. 5. Of having attended to Practical Pharmacy and of having acquired a practical knowledge of the preparation of medicines. These certificates (as is the case also with all the certificates hereinafter mentioned) must be transmitted to the registrar at least fourteen days before the commencement of the examination. Fee for this examination, £5.

Candidates will be examined in the following subjects: Anatomy, Physiology, Histology, Materia Medica and Pharmaceutical Chemistry, and Organic Chemistry.

Every candidate for the July examination, on sending in his name for the examination, must state whether he intends to compete for Honours in any subject or subjects; and, if he does so intend, must specify the subject or subjects. No candidate will be allowed to take both the Pass and the Honours Papers in the same subject; but every candidate must take the Pass Papers in those subjects in which he does not offer himself for Honours. A candidate who enters for, but fails to obtain, Honours in any subject, may be recommended by the examiners for a Pass in that subject if they are satisfied that he has shown such a competent knowledge thereof as is required by the regulations for the Pass Examination.

M.B. Examination.[5]—The M.B. Examination takes place once in each year, and commences on the last Monday in October. Each candidate, two academical years after passing the First Examination, must produce certificates to the following effect:—1. Of having passed the Intermediate Examination. 2. Of having, subsequently to having passed the Intermediate Examination, attended a course of lectures on each of two of the subjects enumerated in Section 2 of the regulations for that examination, and for which the candidate had not on that occasion presented certificates. 3. Of having conducted at least twenty labours. Certificates on this subject will be received from any legally qualified practitioner in Medicine. 4. Of having attended the Surgical Practice of a recognised hospital or hospitals during two years, with clinical instruction and lectures on Clinical Surgery. 5. Of having attended the Medical Practice of a recognised hospital or hospitals during two years, with clinical instruction and lectures on Clinical Medicine. 6. Of having, after having attended Surgical and Medical Hospital Practice for at least twelve months subsequently to passing the Intermediate Examination, attended to Practical Medicine, Surgery, or Obstetric Medicine, with special charge of patients, in a hospital, infirmary, dispensary, or parochial union, during six months, such attendance not to be counted as part of either the Surgical or the Medical Hospital Practice prescribed in Clauses 4 and 5. 7. Of having acquired proficiency in Vaccination. Certificates on this subject will be received only from the authorised vaccinators appointed by the Privy Council. The candidate must also produce a certificate of moral character from a teacher in the last school or institution at which he has studied, as far as the teacher's opportunity of knowledge has extended. The fee for this examination is £5.

[5] Any candidate for the M.B. Examination who has passed the Intermediate Examination under the former regulations will be required to have also passed the examination in Physiology at some previous Intermediate Examination carried on under the present regulations, at which examination he shall not be allowed to compete for Honours.

Candidates will be examined in the following subjects: General Pathology, General Therapeutics and Hygiene, Surgery, Medicine, Obstetric Medicine, Forensic Medicine. The examinations will include questions in Surgical and Medical Anatomy, Pathological Anatomy, and Pathological Chemistry.

Any candidate who has passed the M.B. Examination may be examined at the Honours Examination next following the M.B. Examination at which he has passed for Honours in (1) Medicine, (2) Obstetric Medicine, and (3) Forensic Medicine. The examinations commence in the week following that in which the Pass Examination terminated. Except in the case of Forensic Medicine, they are conducted by means of printed papers, but the examiners will not be precluded from putting *viva-voce* questions upon the written answers of the candidates.

Bachelor of Surgery.—The examination for the degree of Bachelor of Surgery takes place once in each year, and commences on the Tuesday following the first month in December. Candidates must produce certificates to the following effect:—1. Of having passed the examination for the degree of Bachelor of Medicine in this University. 2. Of having attended a course of instruction in Operative Surgery, and of having operated on the dead subject. Fee for this examination, £5.

Any candidate who has passed the B.S. Examination may be examined at the Honours Examination next following the B.S. Examination at which he has passed for Honours in Surgery. The examination takes place on Tuesday in the week following the Pass Examination, and is conducted by means of printed papers.

Master in Surgery.—The examination for the degree of Master in Surgery takes place once in each year, and commences on the first Monday in December.

Candidates must produce certificates to the following effect:—1. Of having taken the degree of Bachelor of Surgery in this University.[6] 2. Of having attended, subsequently to having taken the degree of Bachelor of Surgery in this University, (*a*) to Clinical or Practical Surgery during two years in a hospital or medical institution recognised by this University; or (*b*) to Clinical or Practical Surgery during one year in a hospital or medical institution recognised by this University, and of having been engaged during three years in the practice of his profession; or (*c*) of having been engaged during five years in the practice of his profession, either before or after taking the degree of Bachelor of Surgery in this University. One year of attendance on Clinical or Practical Surgery, or two years of practice, will be dispensed with in the case of those candidates who at the B.S. Examination have been placed in the first division. 3. Of moral character, signed by two persons of respectability.

Fee for this degree, £5. The examination is conducted by means of printed papers and *viva-voce* interrogation.

Candidates will be examined in Logic and Psychology, or in Mental Physiology, and in Surgery.

Doctor of Medicine.—The examination for this degree takes place once in each year, and commences on the first Monday in December.

Candidates must produce certificates to the following effect:—1. Of having passed the examination for the degree of Bachelor of Medicine in this University. 2. Of having attended, subsequently to having taken the degree of Bachelor of Medicine in this University, (*a*) to Clinical or Practical Medicine during two years in a hospital or medical institution recognised by this University; or (*b*) to Clinical or Practical Medicine during one year in a hospital or medical institution recognised by this University, and of having been engaged during three years in the practice of his profession; or (*c*) of having been engaged during five years in the practice of his profession, either before or after taking the degree of Bachelor of Medicine in this University. One year of attendance on Clinical or Practical Medicine or two years of practice will be dispensed with in the case of those candidates who at the M.B. Examination have been placed in the first division. 3. Of moral character, signed by two persons of respectability.

[6] Candidates who have obtained the degree of Bachelor of Medicine previously to 1876 will be admitted to the examination for the degree of Master in Surgery without having taken the degree of Bachelor of Surgery; and in the case of such candidates the attendance on surgical practice required by Regulation 2 may commence from the date of the M.B. degree.

Fee for this degree, £5.[7] The examination is conducted by means of printed papers and *viva-voce* interrogation.

Candidates will be examined in Logic and Psychology, or in Mental Physiology, and in Medicine.

UNIVERSITY OF DURHAM.

A Certificate, two Licences, and three Degrees are conferred—viz., a certificate of Proficiency in Sanitary Science, a Licence in Medicine, and a Licence in Surgery; and the Degrees of Bachelor in Medicine, Master in Surgery, and Doctor in Medicine.

For the degree of *Bachelor in Medicine* (*M.B.*) there are three professional examinations: the first being held in September (in 1887, commencing on the 19th) and April (in 1887, commencing on the 18th); the second in September (in 1887, commencing on the 26th) and April (in 1887, commencing on the 25th; and the third in December (in 1886, commencing on the 6th) and in June (in 1887, commencing on the 13th).

The subjects for the first examination are—Elementary Anatomy and Elementary Physiology, Chemistry, with Physics, and Botany. Candidates must produce the following certificates:—(1) Of registration as a medical student. (2) Of attendance on the following courses of lectures: Anatomy, Physiology, Chemistry, with Physics, and Practical Anatomy (Dissections), each six months; Botany and Practical Chemistry, each three months. The subjects for the second examination are Anatomy, Physiology, Materia Medica, with Pharmacy. For it the following certificates are necessary: Lectures, &c.—Anatomy, Physiology, Practical Anatomy (Dissections), second courses of six months each; Materia Medica, Practical Physiology, and Practical Pharmacy, courses of three months each. The candidate must also produce a certificate of his having passed the first examination for the M.B., or the first examination of the Conjoint Board of the Royal College of Physicians of London, and the Royal College of Surgeons of England, together with the extra examinations in Chemistry and Botany of the University of Durham.

The subjects for the third examination are Medicine, Surgery, Pathology, Therapeutics, Midwifery and Diseases of Women and Children, Medical Jurisprudence, and Public Health. For it candidates must produce the following certificates—viz.: 1. Of being not less than twenty-one years of age. 2. Of good moral character. 3. Of having passed one of the following examinations in Arts: (*a*) the examination for graduation in Arts at one of the following universities—Oxford, Cambridge, Durham, Dublin, London, Queen's (Ireland), Edinburgh, Glasgow, St. Andrews, Aberdeen, Calcutta, Madras, Bombay, McGill College (Montreal), Queen's College (Kingston), Victoria (Manchester), and Royal (Ireland); or (*b*) the Preliminary or Extra-professional Examination for graduation in Medicine at one of the following universities—Cambridge, London, Edinburgh, Glasgow, St. Andrews, Aberdeen, Queen's (Ireland), Victoria (Manchester), and Royal (Ireland); or (*c*) the Preliminary Examination in Arts qualifying for the Membership of the Royal College of Physicians of London or for the Fellowship of the Royal College of Surgeons of England; or (*d*) the Preliminary Examination in Arts for the degrees in Medicine of the University of Durham (in 1887, commencing on March 22nd and September 20th). 4. Of attendance on the following course of lectures—viz.: Medicine and Surgery, each two courses of six months; Public Health, one course; Forensic Medicine, Midwifery and Diseases of Women and Children, and Pathology, each one course of three months; Clinical Medical and Clinical Surgical Lectures, each two winters and two summers; Medical Hospital Practice and Surgical Hospital Practice and Post-mortem Demonstrations, each three winters and two summers; Medical Clinical Clerking and Surgical Dressing, each six months; Clinical Obstetrics, three months; attendance on not less than twenty-one cases of Midwifery, and instruction in Vaccination.

N.B.—It is required that one of the four years of professional education shall be spent in attendance at the College of Medicine, Newcastle-on-Tyne. Candidates for the First Examination who have passed the First Examination of the Conjoint Board in England, and candidates who hold a qualification from a recognised Licensing Body in the United Kingdom, will be exempt from the First Examination of the University, except in the subjects of Chemistry, with Physics and Botany. Candidates who have passed the First and Second Examinations of the University will be exempt from the First and Second Examinations of the Conjoint Board.

For the degree of *Master in Surgery* (*M.S.*), the candidate must have passed the examination for the degree of Bachelor in Medicine and must have attended one course of lectures on Operative Surgery. Each candidate will have an additional paper on Surgery and additional clinical and *viva-voce* examinations, and will have to perform operations on the dead body.

For the degree of *Doctor of Medicine* (*M.D.*), candidates must not be less than twenty-four years of age, must have obtained the degree of M.B. at least two years previously, and in the interim have been engaged in medical and surgical practice. Each candidate will be required to write an essay on some medical subject selected by himself and approved by the Professor of Medicine, and to pass an examination thereon.

Candidates for any of the above degrees must give at least twenty-eight days' notice to the registrar of the College.

VICTORIA UNIVERSITY, MANCHESTER.

Colleges of the University: Owens College, Manchester, and University College, Liverpool.

Three degrees in Medicine and Surgery are conferred by the Victoria University—viz.; Bachelor of Medicine (M.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.).

All candidates for degrees in Medicine and Surgery are required (1) To have matriculated in the University; and (2) to pass an examination called the Entrance Examination in Arts, or to have passed such other examination as may be recognised by the University for this purpose.[8]

Degree of Bachelor of Medicine.—Before admission to the degree of M.B. candidates are required to present certificates that they will have attained the age of twenty-one years on the day of graduation, and that they have pursued the courses of study required by the University Regulations during a period of not less than four years subsequently to the date of their registration by the General Medical Council, two of such years having been passed in a College of the University, and one year at least having been passed in a College of the University subsequently to the date of passing the Preliminary Examination in Science. All candidates for the degree of Bachelor of Medicine are required, after matriculating, to satisfy the examiners in the several subjects of the following examinations—the Preliminary Examination in Science, the Intermediate Examination for the degree of M.B., and the Final Examination for the degree of M.B.

The Preliminary Examination in Science.—The subjects of examination are as follows:—1. Chemistry. 2. Elementary Biology. 3. Physics. Candidates for the Preliminary Examination in Science must have attended during at least one year courses, both of lectures and of laboratory work, in each of the above-named subjects.

The Intermediate M.B. Examination.—The subjects of examination are as follows:—1. Anatomy. 2. Physiology (including Physiological Chemistry and Histology). 3. Materia Medica and Pharmacy. Candidates for the Intermediate M.B. Examination are required to have passed the Preliminary Examination in Science and to have attended courses of instruction in Anatomy for one winter session, in Physiology for two winter sessions (but one session will be accepted provided that not less than one hundred class attendances are presented by the candidate), and in Materia Medica and Pharmacy for one summer session. The certificates must show (1) that the human body has been dissected twice at least; (2) that laboratory instruction has been received in Physiology; (3) that practical instruction has been received in Materia Medica and Pharmacy.

The Final M.B. Examination.—The examination is divided into two parts, called the First Part and the Second

[7] This fee will continue to be £10 to all such as, having taken their M.B. degree under the former regulations, shall not have paid the fee of £5 at the Preliminary Scientific Examination.

[8] The Examinations at present recognised are:—1. The Preliminary Examination of the Victoria University provided Latin and Mechanics have been taken up. 2. The Matriculation Examination of the University of London. 3. The Previous Examination of the University of Cambridge. 4. Responsions and Moderations of the University of Oxford. 5. The Leaving Certificate Examination of the Oxford and Cambridge Boards, provided that it include Latin, English, Mathematics, and Elementary Mechanics. 6. The Final Examination for Graduation in Arts of any University in Great Britain and Ireland.

part respectively, which may be passed separately or on the same occasion, but the First Part cannot be taken before the end of the third year, and the Second Part cannot be taken before the end of the fourth year, of medical study in accordance with the University Regulations. The subjects of examination are as follows:—Part I.: 1. Systematic Surgery. 2. Pharmacology and Therapeutics. 3. General Pathology. Part II.: 1. Systematic and Clinical Medicine, including Mental Diseases. 2. Practical and Clinical Surgery. 3. Obstetrics and Diseases of Women and Children. 4. Morbid Anatomy. 5. Forensic Medicine. 6. Hygiene.

Candidates, before presenting themselves for the Final Examination, are required to have passed the Intermediate Examination, and to furnish certificates—1. Of having attended the Medical and Surgical Practice of a hospital or hospitals, approved by the University, during at least three years, of which years two at least must be subsequently to the date of passing the Intermediate Examination, except when exemption has been granted by the General Board of Studies, after report from the Departmental Board of Medical Studies. 2. Of having attended during at least twelve months demonstrations in the post-mortem theatre of a hospital. 3. Of having attended, under proper supervision, at least twenty cases of labour. 4. Of having during at least three months received in either a general or a special hospital, approved by the University, such Clinical instruction in the Diseases peculiar to Women as shall be approved by the University. 5. Of having acquired proficiency in Vaccination. 6. Of having attended courses of instruction, approved by the University, in a College of the University or in a College or Medical School recognised for this purpose by statute of the University, in the following subjects:—(*a*) Systematic Medicine, (*b*) Clinical Medicine, (*c*) Systematic Surgery, (*d*) Practical Surgery, (*e*) Clinical Surgery, (*f*) Obstetrics and Diseases of Women and Children, (*g*) Pharmacology and Therapeutics, (*h*) General Pathology and Morbid Anatomy, (*i*) Forensic Medicine, (*j*) Hygiene.

Degree of Doctor of Medicine.—Candidates are not eligible for the degree of Doctor of Medicine unless they have previously received the degree of Bachelor of Medicine, and at least one year has elapsed since they passed the examination for that degree. Candidates for the degree of Doctor of Medicine are required to present a printed dissertation embodying the results of personal observations or original research, either in some department of medicine or of some science directly relative to medicine. No candidate will be admitted to the degree unless his dissertation, after report from the Departmental Board of Medical Studies, shall have been recommended by the General Board of Studies to the Council for acceptance in that behalf. Candidates may be examined on any subject connected with their dissertations.

Degree of Master of Surgery.—Candidates are not eligible for the degree of Master of Surgery unless they have previously received the degree of Bachelor of Medicine, and at least one year has elapsed since they passed the examination for that degree.

The subjects of examination are as follows: (1) Surgical Anatomy, (2) Surgical Pathology, (3) Practical Surgery, including the performance of operations on the dead body, (4) Clinical Surgery, (5) Ophthalmology.

UNIVERSITY OF EDINBURGH.

Three medical degrees are conferred by the University of Edinburgh—namely, Bachelor of Medicine (M.B.), Master in Surgery (C.M.), and Doctor of Medicine (M.D.). The degree of Master in Surgery is not conferred on any person who does not also at the same time obtain the degree of Bachelor of Medicine.

No one is admitted to the degrees of Bachelor of Medicine and Master in Surgery who has not been engaged in medical and surgical study for four years—the medical session of each year, or *annus medicus*, being constituted by at least two courses of not less than one hundred lectures each, or by one such course and two courses of not less than fifty lectures each; with the exception of the clinical courses, in which lectures are to be given at least twice a week during the prescribed periods.[9]

Every candidate for the degrees of M.B. and M.C. must give sufficient evidence by certificates—(*a*) That he has studied each of the following departments of medical science—namely, Anatomy, Chemistry, Materia Medica, Institutes of Medicine or Physiology, Practice of Medicine, Surgery, Midwifery and the Diseases peculiar to Women and Children, and General Pathology, each during courses including not less than one hundred lectures; Practical Anatomy, a course of the same duration as those of not less than one hundred lectures;[10] Practical Chemistry, three months; Practical Midwifery, three months at a midwifery hospital, or a certificate of attendance on six cases from a registered medical practitioner; Clinical Medicine, Clinical Surgery,[11] courses of the same duration as those of not less than one hundred lectures, or two courses of three months' lectures, being given at least twice a week; Medical Jurisprudence, Botany, Natural History (including Zoology), during courses including not less than fifty lectures. (*b*) That he has attended, for at least two years, the medical and surgical practice of a general hospital which accommodates not fewer than eighty patients, and possesses a distinct staff of physicians and surgeons. (*c*) That he has attended, during a course of not less than fifty hours' instruction, the class of Practical Materia Medica in the University of Edinburgh, or a similar class conducted in a university or recognised school of medicine, or a similar class conducted by a teacher recognised by the University Court; or that he has been engaged, for at least three months, by apprenticeship or otherwise, in compounding and dispensing drugs at the laboratory of a hospital or dispensary, by a member of a surgical college or faculty, a licentiate of the London or Dublin Society of Apothecaries, or a member of the Pharmaceutical Society of Great Britain. (*d*) That he has attended, for at least six months, by apprenticeship or otherwise, the out-door practice of a hospital, or the practice of a dispensary physician, a surgeon, or a member of the London or Dublin Society of Apothecaries.

Students of Medicine in the London schools, and in the school of the College of Surgeons in Dublin, can obtain there two *anni medici* out of the four required for the Edinburgh degrees in Medicine. One *annus medicus* may be constituted by attendance on Practical Anatomy and Hospital Practice during the winter session. Another *annus medicus* by attending either (*a*) full winter courses on any two of the following subjects—Anatomy, Physiology, Chemistry, Pathology, Surgery, Medicine, Clinical Surgery, Clinical Medicine; or (*b*) on one such course and two three months' courses on any of the following subjects—Botany, Practical Chemistry, Natural History, Medical Jurisprudence. If the student selects the arrangement prescribed in (*a*), attendance on a third course, although unnecessary to constitute an *annus*, will also be accepted. The other subjects and the additional courses, not given in London or Dublin, necessary for the degrees of the University, require to be attended at this University. In provincial schools, where there are no lecturers recognised by the University Court, a candidate can only have one *annus medicus*, and this is constituted by attendance at a qualified hospital along with a course of Practical Anatomy. But in a provincial school where there are two or more lecturers recognised by this University, a second *annus medicus* may be made by attendance on at least two six months', or one six months' and two three months', recognised courses.

Every candidate must deliver, before the 31st day of March of the year in which he proposes to graduate, to the Dean of the Faculty of Medicine a declaration in his own handwriting, that he has completed his twenty-first year, or that he will have done so on or before the day of graduation, and that he will not be, on the day of graduation, under articles of apprenticeship to any surgeon or other master; together with a statement of studies, accompanied with proper certificates.

Each candidate is examined, both in writing and orally, on Chemistry, Botany, and Natural History; on Anatomy, Institutes of Medicine, Materia Medica (including Practical Pharmacy), and Pathology; on Surgery, Practice of Medi-

[9] No course of lectures will be allowed to qualify unless the lecturer certifies that it has embraced at least one hundred lectures, or fifty lectures, in conformity with the requirements of this section. Three months' courses on Materia Medica, Pathology, and Midwifery do not qualify.

[10] Certificates of attendance on Practical Anatomy must express not only the number of months engaged in dissection, but the names of the parts dissected, and the degree of care with which the dissections have been made. Students are recommended not to appear for an examination in Anatomy with a view to a degree until they have dissected the human body at least once.

[11] The Medical Faculty recommend that medical students should not attend Clinical Surgery during their first six months' attendance on Clinical Medicine.

cine, Midwifery, and Medical Jurisprudence; clinically, on Medicine and on Surgery in a hospital. The examinations on Anatomy, Chemistry, Institutes of Medicine, Botany, Natural History, Materia Medica, and Pathology are conducted, as far as possible, by demonstrations of objects placed before the candidates.

Students who have passed their examination on the first division of these subjects may be admitted to examination on the second division at the end of their third year.

The examination on the third and fourth divisions cannot take place until the candidate has completed his fourth *annus medicus*.

Candidates may, if they choose, be admitted to examination on the first two of these divisions at the end of their third year, or to the fourth examinations at the end of their fourth year.

The degree of Doctor of Medicine may be conferred on any candidate who has obtained the degrees of Bachelor of Medicine and Master in Surgery, and who is of the age of twenty-four years, and produces a certificate of having been engaged, subsequently to his having received the degrees of M.B. and C.M., for at least two years in attendance on a hospital, or in the military or naval medical service, or in medical and surgical practice; provided always that the degree of M.D. shall not be conferred on any person unless he be a graduate in Arts of one of the universities of England, Scotland, or Ireland, or of such other universities as are above specified, or unless he shall, before or at the time of his obtaining the degrees of M.B. and C.M., or thereafter, have passed a satisfactory examination on *three* of the subjects mentioned in Section II. of the statutes relative to preliminary examination. Two of these must be Greek and Logic or Moral Philosophy, and the third is to be one of the following subjects, at the option of the candidate—namely, French, German, Higher Mathematics, and Natural Philosophy; and provided also that the candidate for the degree of M.D. shall submit to the Medical Faculty a thesis, certified by him to have been composed by himself, and which shall be approved by the Faculty, on any branch of knowledge comprised in the professional examinations for the degrees of M.B. and C.M., which he may have made a subject of study after having received that degree.

The fees for M.B. and C.M. are £22. Total fees and stamp for graduating as M.D. only, by regulations for students commencing before February, 1861, £25. The fees for examination must be paid at the secretary's office ten days before the dates thereof, and the fees for the degree of M.D. and the stamp duty for the latter must be paid on or before the 15th day of July in the year of graduation. In the event of the candidate not passing any one of the professional examinations the fee is not returned; but he may appear at one subsequent examination without paying an extra fee, and at any future examination on paying one-half the fee.

UNIVERSITY OF GLASGOW.

Three degrees in Medicine are granted viz., Bachelor of Medicine, Master in Surgery, and Doctor of Medicine. The curricula of study and the examinations for the several degrees conferred are nearly the same as in the University of Edinburgh. The annual term for conferring medical and surgical degrees is the 1st of August. The Preliminary Examinations of medical students in branches of general education begin on the 6th of October, 1886, and on the 30th of March, 1887.

The fees for the degrees are £21 for M.B. and C.M., which are obtained together, and £15 for M.D.

The regulations under which the above degrees are granted and the notices of the subjects of examination may be obtained by application to the assistant-clerk, Matriculation Office, the University.

After the present winter session the examinations in the first, second, and third groups of subjects of the professional examinations for degrees will be held in July instead of October, as at present.

UNIVERSITY OF ABERDEEN.

The curricula for the several degrees conferred are nearly the same as in the University of Edinburgh.

Professional Examinations will be held twice in each year—namely, in April and July, directly after the close of the winter and summer sessions.

The fees for graduation are the same as in the University of Edinburgh. Matriculation fee, including all dues, for the winter and summer sessions, £1; summer session alone, 10s.

Candidates who commenced their medical studies before November, 1861, are entitled to appear for examination for the degree of M.D. after four years' study, one of which must have been in the University of Aberdeen.

Besides the Royal Infirmary, students have the opportunity of attending the following institutions: Sick Children's Hospital; General Dispensary, and Lying-in and Vaccine Institutions, daily; Royal Lunatic Asylum; Eye Institution, in which is given clinical instruction on the Diseases of the Eye, and on the Application of the Ophthalmoscope for their diagnosis.

Application for further information should be addressed to the Dean of the Medical Faculty.

UNIVERSITY OF ST. ANDREWS.

Two degrees in Medicine are granted—namely, Bachelor of Medicine and Master in Surgery (M.B., C.M.), and Doctor of Medicine (M.D.). The curricula for these degrees, and the regulations under which they are conferred, differ from those of the University of Edinburgh only in the particulars noticed below.

The degree of *Doctor of Medicine* may be conferred by the University of St. Andrews on any registered medical practitioner above the age of forty years whose professional position and experience are such as, in the estimation of the University, to entitle him to that degree, and who shall, on examination, satisfy the medical examiners of the sufficiency of his professional knowledge; provided always that degrees will not be conferred under this section on a greater number than ten in any one year. The examinations are held yearly towards the end of April. Candidates must lodge with the Dean of the Medical Faculty the following certificates, along with application for admission to examination:—1. A certificate of age, being a baptismal certificate or an affidavit of age. 2. Holograph certificates from at least three medical men of acknowledged reputation in the medical profession or in the medical schools, recommending the candidate to the Senatus for the degree, and testifying to his professional skill and position. As only ten can graduate yearly, candidates will be selected whose service and certificates seem to the Medical Faculty to present the highest professional claims, and where these seem equal preference will be given to age and priority of application. 3. A portion of the graduation fee (viz., £10 10s.) shall be forfeited should the candidate fail to appear or to graduate at the time appointed. A satisfactory examination, written and *viva-voce*, must be passed in the following departments—viz., Materia Medica and General Therapeutics, Medical Jurisprudence, Practice of Medicine and Pathology, Surgery, Midwifery, and Diseases of Women and Children.

No one will be received as a candidate for the degree of *Bachelor of Medicine and Master in Surgery* unless two years at least of his four years of medical and surgical study shall have been in one or more of the following universities or colleges—viz., the Universities of St. Andrews, Glasgow, Aberdeen, Edinburgh, Oxford, and Cambridge; Trinity College, Dublin; Queen's College, Belfast; Queen's College, Cork; and Queen's College, Galway.

Subject always to the condition here specified, the studies for candidates for the degree of Bachelor of Medicine and Master in Surgery will be under the following regulations. The remaining years of medical and surgical study may be either in one or more of the universities and colleges above specified, or in the hospital schools of London, or in the school of the College of Surgeons of Dublin, or under such private teachers of medicine as may from time to time receive recognition from the University Court. Attendance during at least six winter months on the medical or surgical practice of a general hospital which accommodates at least eighty patients, and during the same period on a course of Practical Anatomy, may be reckoned as one of such remaining years.

Every candidate for examination for the degree of M.B. and C.M. is required to lodge a declaration of age, a statement of his course of study, his inaugural dissertation, and all his certificates with the Dean of the Medical Faculty, on or before the 25th of March in each year.

UNIVERSITY OF DUBLIN (TRINITY COLLEGE).

Matriculation.—All students in the School of Physic intending to practise Physic must be matriculated, for which a fee of 5*s.* is payable. No student can be admitted for the winter course after Nov. 25th.

Previous Medical Examination.—Candidates for degrees and licences in Medicine and Surgery are required to pass a previous examination in Physics, Chemistry, Botany, Comparative Anatomy, Descriptive Anatomy, and Institutes of Medicine (Practical Histology and Physiology) previously to their degree examination.

Bachelor in Medicine.—A candidate for this degree must be a graduate in Arts, and may obtain the degree of Bachelor in Medicine at the same Commencements as that at which he receives his degree of B.A., or at any subsequent Commencements. The medical education of a Bachelor in Medicine is of four years' duration, and comprises attendance on a single course of each of the following lectures—Anatomy, Practical Anatomy, Theory of Surgery, Chemistry, Materia Medica and Pharmacy, Physiology, Practice of Medicine, Midwifery, Botany, Medical Jurisprudence, Heat, Electricity, Magnetism, Comparative Anatomy; three courses of nine months' attendance on the Clinical Lectures of Sir Patrick Dun's or other metropolitan hospital recognised by the Board of Trinity College; six months' instruction in Practical Midwifery, including Clinical Lectures; a certificate of personal attendance on Fever cases, with names and dates of cases. Six months' dissections, three months' laboratory instruction in Chemistry, three months' Practical Histology, and one month's instruction in Vaccination are required. Any of the above-named courses may be attended at any medical school in Dublin recognised by the Provost and Senior Fellows. Fee for the *Liceat ad Examinandum*, £5; for the M.B. degree, £11.

Doctor in Medicine.—A Doctor in Medicine must be M.B. of at least three years' standing, or have been qualified to take the degree of M.B. for three years, and must read a thesis or undergo an examination before the Regius Professor of Physic, in accordance with the rules and statutes of the University. Total amount of fees for this degree, £13.

Bachelor in Surgery.—A Bachelor in Surgery must be a Bachelor in Arts and in Medicine, and have spent four years in the study of Surgery and Anatomy. He must also pass a public examination in the Hall before the Professors of the School of Physic, having previously completed the prescribed curriculum of study, which includes the following additions to the courses named above for the M.B.: Operative Surgery, Two Courses of Dissections, Ophthalmic Surgery.[12] Candidates are required to perform surgical operations on the dead subject. Fee for the *Liceat ad Examinandum*, £5; for the degree of Bachelor in Surgery, £5.

Master in Surgery.[13]—A Master in Surgery must be a Bachelor in Surgery of three years' standing, or have been qualified to take the degree of Bachelor in Surgery for three years; and must read a thesis publicly before the Regius Professor of Surgery, or undergo an examination before the Regius Professor, according to regulations to be approved by the Provost and Senior Fellows. Fee for the degree of Master in Surgery, £11.

University Licences.—Candidates for the licences in Medicine or Surgery must be matriculated in Medicine, and must have completed two years in Arts and four years in medical studies.

Licentiate in Medicine.—The medical course and examination necessary for the licence in Medicine are the same as for the degree of M.B. Fee for the *Liceat ad Examinandum*, £5; for the licence in Medicine, £5.

Licentiate in Surgery.—The surgical course and examination necessary for the licence in Surgery are the same as for the degree of Bachelor in Surgery. Fee for the *Liceat ad Examinandum*, £5; for the licence in Surgery, £5.

The total cost of the education and first degrees in Medicine and Surgery is as follows, in addition to the fees for education in Arts and B.A. degree (£83 4*s.*); Medical and Surgical Lectures, £60 13*s.* 6*d.*; Hospitals, £44 2*s.*; Medical and Surgical Examinations and Degrees, £26.

[12] Students in the School of Physic who matriculated before June 22nd, 1872, may obtain the degree of Master in Surgery according to the regulations in force previously to the creation of the degree of Bachelor in Surgery.

[13] Masters in Surgery must be of the standing of Master of Arts.

ROYAL UNIVERSITY OF IRELAND.

The following degrees are conferred by the University in this Faculty: Bachelor of Medicine, Doctor of Medicine, Master of Surgery, Master of Obstetrics; in Sanitary Science, a special diploma. All the medical examinations are held twice yearly—viz., towards the end of April and in October.

The course for degrees in Medicine &c. is one of at least four years' duration. Students who have commenced their medical studies since January 1st, 1884, must also produce a certificate of having been registered as students in Medicine by the Medical Council for a period of at least forty-five months. No one can be admitted to any degree in Medicine who is not fully twenty-one years of age. All candidates for these degrees are, in addition to attending the lectures and complying with the other conditions to be from time to time prescribed, required to pass the following examinations: the Matriculation Examination, the First University Examination, the First Examination in Medicine, the Second Examination in Medicine, and the Degree Examination.

The First Examination in Medicine.—Students are admitted to this examination after the lapse of one academical year from the time of their matriculation. The subjects of this examination are—Zoology, Botany, and a modern language (either French or German). Candidates who have passed in a modern language at the First University Examination in Arts are exempt from again presenting this subject at the First Examination in Medicine, except as a qualification for admission to compete for Honours, the answering of the candidates in the three subjects above-mentioned being taken into account in awarding Honours.

The Second Examination in Medicine.—Students are admitted to this examination after the lapse of one academical year from the time of passing the First Examination in Medicine, provided they have completed the First Period of the Course of Medical Studies. The subjects of this examination are—Anatomy, Physiology, Materia Medica (Pharmacology), and Chemistry.

The Examination for the Degree of M.B.—Students are admitted to this examination after the lapse of one academical year from the time of passing the Second Examination in Medicine, provided they have completed the Second Period of the Course of Medical Studies. The subjects of this examination are—Anatomy, including Practical Anatomy; Physiology, including Practical Physiology and Histology; Surgery, Midwifery, and Diseases of Women and Children; Vaccination; Theory and Practice of Medicine, Medical Jurisprudence; Mental Diseases.

M.D. Degree.—Candidates may be admitted to this degree after the lapse of two academical years from the time of obtaining the degree of M.B.; provided, however, that all persons who were students in Medicine in the Queen's University at the date of its dissolution shall be entitled, if they so desire, to obtain the degree of M.D., instead of the degree of M.B., upon passing the examination herein prescribed for the M.B. degree. Every candidate will be examined at the bedside, and required to diagnose at least six cases, medical and surgical, and prescribe treatment, and to write detailed reports on at least two cases to be selected by the examiners, and to discuss all the questions arising thereon. Every candidate must submit to the medical examiners, for their approval, a thesis certified by him (or her) to have been composed by himself (or herself). No thesis will be approved which does not contain some original or personal observations in Practical Medicine, Surgery, Midwifery, or in some of the sciences embraced in the curriculum, or else a full digest and critical exposition of the opinions and researches of others on the subject selected by the candidate, accompanied by precise references to the publications quoted.

The *M.Ch. Degree* will be conferred only on graduates in Medicine of the University. The examination will comprise the Theory and Practice of Surgery, including Operative and Clinical Surgery.

The *M.A.O. Degree* will also be conferred only on graduates in Medicine of the University. The examination will comprise the Theory and Practice of Midwifery, and the use of Obstetrical Instruments and appliances. Candidates will be required to undergo a special written examination in Midwifery, Gynæcology, and Diseases of Children, in addition to the other tests.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

The licence of this College is a qualification to practise Medicine, Surgery, and Midwifery, and is recognised by the Local Government Board as a qualification in Surgery as well as in Medicine.

Licentiates.—Every candidate for the College licence (except when otherwise provided by the bye-laws) is required to produce satisfactory evidence to the following effect:—Of having attained the age of twenty-one years. Of moral character. Of having passed before the commencement of professional study an examination in the subjects of general education recognised by the General Medical Council. Of having been registered as a medical student in a manner prescribed by the General Medical Council. Of having been engaged in professional studies during at least forty-five months, of which at least three winter sessions and two summer sessions shall have been passed at a recognised medical school or schools, and one winter session and two summer sessions in one or other of the following ways:—

1. Attending the practice of a hospital or other institution recognised by the College for that purpose. 2. Receiving instruction as the pupil of a legally qualified practitioner having opportunities of imparting a practical knowledge of Medicine, Surgery, or Midwifery. 3. Attending lectures on any of the required subjects of professional study at a recognised place of instruction. Of having attended, during three winter sessions and two summer sessions, the medical and surgical practice at a recognised hospital or hospitals.[14] Of having discharged the duties of a medical clinical clerk during six months, and of a surgical dresser during other six months; and of having been engaged during six months in the clinical study of Diseases peculiar to Women. Of having received instruction in Chemistry, Practical Chemistry, Materia Medica, and Practical Pharmacy. Of having attended a course of lectures on the following subjects:—Anatomy (with dissections), during twelve months; Physiology; a practical course of General Anatomy during a winter or a summer session, consisting of not less than thirty meetings of the class; Pathological Anatomy; Principles and Practice of Medicine; Principles and Practice of Surgery; Midwifery and the Diseases peculiar to Women; Forensic Medicine. Of having attended Clinical Lectures on Medicine during nine months, and also Clinical Lectures on Surgery during nine months, and of having been engaged during a period of three months in the Clinical Study of Diseases peculiar to Women. Of having passed the professional examinations, of which there are three, each partly written, partly oral, and partly practical. The subjects of the first examination are:—Chemistry, including Chemical Physics—viz., Heat, Light, and Electricity; Materia Medica and Pharmacy; and Osteology. The subjects of the second examination are Anatomy and Physiology. The subjects of the final examination are Medical Anatomy and Pathology, including Morbid Anatomy; the Principles and Practice of Medicine; Surgical Anatomy and Pathology, including Morbid Anatomy; the Principles and Practice of Surgery; Midwifery and Diseases peculiar to Women; Forensic Medicine; Public Health and Therapeutics.

Any candidate who shall produce satisfactory evidence of having passed an examination on Anatomy and Physiology, conducted by a university in the United Kingdom, in India, or in a British colony, or by the College of Surgeons in England, Scotland, or Ireland, or the Faculty of Physicians and Surgeons of Glasgow, shall be exempt from re-examination on those subjects. Any candidate who shall produce satisfactory evidence of having passed an examination on Chemistry and Materia Medica, required for a degree in Medicine at a university in the United Kingdom, in India, or in a British colony, will be exempted from re-examination on those subjects. Any candidate who shall have obtained a degree in Surgery at a university in the United Kingdom, after a course of study and an examination satisfactory to the College, shall be exempt from re-examination on Surgical Anatomy and on the Principles and Practice of Surgery. Any candidate who shall have passed the examination on Surgery conducted by the Royal College of Surgeons of England, or the Royal College of Surgeons of Edinburgh, or the Royal College of Surgeons in Ireland, or the Faculty of Physicians and Surgeons of Glasgow, after a course of study and an examination satisfactory to the College, shall be exempt from re-examination on Surgical Anatomy and on the Principles and Practice of Surgery.

[14] A three months' course of clinical instruction in the wards of a recognised lunatic hospital or asylum may be substituted for the same period of attendance in the medical wards of a general hospital.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

REGULATIONS RESPECTING THE EDUCATION AND EXAMINATIONS APPLICABLE TO CANDIDATES FOR THE DIPLOMA OF MEMBER OF THE COLLEGE.

Professional Education.—The following are recognised modes of commencing professional education:—(1) Attendance on the practice of a hospital, or other public institution recognised by this College for that purpose. (2) Instruction as the pupil of a legally qualified surgeon, holding the appointment of surgeon to a hospital, general dispensary, or union workhouse, or where such opportunities of practical instruction are afforded as shall be satisfactory to the Council. (3) Attendance on lectures on Anatomy, Physiology, or Chemistry, by lecturers recognised by this College.

Candidates, prior to their admission to the First or Primary Examination on Anatomy and Physiology, will be required to produce the following certificates, viz.:—Of having, prior to the commencement of professional study, been registered by the General Medical Council. Of having attended lectures on Anatomy during two winter sessions. Of having performed dissections during not less than two winter sessions. Of having attended lectures on General Anatomy and Physiology[15] during one winter session. Of having attended a practical course of General Anatomy and Physiology[15] during another winter or a summer session, consisting of not less than thirty meetings of the class.

Candidates who commenced their professional studies on or after October 1st, 1882, and shall have pursued those studies in recognised medical schools in England, will be required, before presenting themselves for the Primary or Anatomical and Physiological Examination for the diploma of Member of the College, to produce certificates of having passed an examination in Elementary Anatomy and Physiology, such examination to be conducted by their teachers at the several medical schools. (1) The periods at which the examination shall be held will be determined by the teachers at the several medical schools, provided that an interval of not less than six months shall elapse between the date at which the candidates shall have passed the examination and the date of their presenting themselves for the Primary Examination at the College. (2) It shall be left to the teachers at the several medical schools to determine the nature and extent of the examination in Elementary Anatomy and Physiology.

Candidates, prior to their admission to the Second or Pass Examination on Surgical Anatomy and the Principles and Practices of Surgery, Medicine, and Midwifery, will be required to produce the following certificates—viz.: Of being twenty-one years of age. Of having been engaged, subsequently to the date of registration by the General Medical Council, during four years, or during a period extending over not less than four winter and four summer sessions, in the acquirement of professional knowledge. Of having attended lectures on surgery during one winter session. Of having attended a course of Practical Surgery during a period occupying not less than six months prior or subsequent to the course required by the preceding Clause 3.[17] Of having attended one course of lectures on each of the following subjects — viz.: Chemistry,[18] Materia Medica, Medicine,

[15] By the Practical Course referred to in Clause 5, it is meant that the learners themselves shall, individually, be engaged in the necessary experiments, manipulations, &c.; but it is not hereby intended that the learners shall perform vivisections.

[16] The certificates of attendance on the several courses of lectures must include evidence that the student has attended the practical instructions and examinations of his teacher in each course.

[17] The course of Practical Surgery referred to in Clause 4 is intended to embrace instruction in which each pupil shall be exercised in practical details, such as in the application of anatomical facts to surgery, on the living person or on the dead body; the methods of proceeding and the manipulations necessary in order to detect the effects of diseases and accidents on the living person or on the dead body; the performance, where practicable, of the operations of surgery on the dead body; the use of surgical apparatus; the examination of diseased structures as illustrated in the contents of a museum of morbid anatomy and otherwise.

[18] The course of lectures on Chemistry included in Clause 5 will not be required in the case of a candidate who shall have passed a satisfactory examination in this subject in his preliminary examination.

Forensic Medicine. Midwifery (with practical instruction), and a certificate of having personally conducted not less than ten labours, and Pathological Anatomy during not less than three months. Of having studied Practical Pharmacy during three months. Of having attended a three months' course of Practical Chemistry (with manipulations), in its application to medical study.[19] Of instruction and proficiency in the practice of Vaccination.[20] Of having attended, at a recognised hospital or hospitals, the Practice of Surgery, during three winter[21] and two summer[22] sessions. Of having been individually engaged, at least twice in each week, in the observation and examination of patients at a recognised hospital or hospitals, under the direction of a recognised teacher, during not less than three months.[23] Of having, subsequently to the first winter session of attendance on Surgical Hospital Practice, attended at a recognised hospital or hospitals, Clinical Lectures on Surgery, during two winter and two summer sessions. Of having been a dresser at a recognised hospital, or of having, subsequently to the completion of one year's professional education, taken charge of patients under the superintendence of a surgeon during not less than six months, at a hospital, general dispensary, or parochial or union infirmary recognised for this purpose, or in such other similar manner as, in the opinion of the Council, shall afford sufficient opportunity for the acquirement of Practical Surgery. Of having attended during the whole period of attendance on Surgical Hospital Practice (see Clause 9) demonstrations in the post-mortem rooms of a recognised hospital. Of having attended, at a recognised hospital or hospitals, the Practice of Medicine, and Clinical Lectures on Medicine, during one winter and one summer session.

Special Notice.—Candidates commencing their professional education on or after the 1st of October, 1882, will not be admitted to the Second or Pass Examination until after the expiration of two years from the date of their passing the Primary or Anatomical and Physiological Examination for such diploma, except in the following cases:—When a candidate, before presenting himself for the Primary Examination, shall possess a recognised degree or diploma in Medicine or Surgery, or shall have completed the curriculum of professional education for the diploma. In the case of a candidate who, being desirous of obtaining the Fellowship, shall fail to present himself for the Primary Examination for the Membership at the end of his second year of professional study, but who shall pass at the end of his third winter session the Primary Examination for the Fellowship, it being required in such case that not less than one year of attendance on the Surgical Practice of a recognised hospital shall intervene between the date of his passing the Primary Examination for the Fellowship and the date of his presenting himself for the Second or Pass Examination for the diploma of Member. In the case of a candidate who, having commenced his professional studies by attendance on the practice of a recognised provincial or colonial hospital, and having completed a year of such attendance, shall fail to pass the Primary Examination at the end of his second winter session of attendance at a recognised medical school, provided that in his case not less than one year shall elapse between the date of his passing the Primary Examination and the date of his presenting himself for the Second or Pass Examination for the diploma of Member. When a candidate, owing to illness, duly certified by one or more of the teachers of his medical school, shall be prevented from presenting himself for the Primary Examination on the completion of his second year of professional study. And in the case of a candidate who, from some unforeseen circumstances, shall fail to present himself for the Primary Examination on the completion of his second year of professional study, it being left to the Court of Examiners to determine whether in such case the candidate shall or shall not be required to comply with the regulation.

Certificates of attendance upon the practice of a recognised provincial or colonial hospital unconnected with, or not in convenient proximity to, a recognised medical school will not be received for more than one winter and one summer session of the hospital attendance required by the regulations of this College. Those candidates who shall have pursued the whole of their studies in Scotland or Ireland will be admitted to examination upon the production of the several certificates required respectively by the College of Surgeons of Edinburgh, the Faculty of Physicians and Surgeons of Glasgow, and the College of Surgeons in Ireland from candidates for their diploma, together with a certificate of instruction and proficiency in the practice of Vaccination, and satisfactory evidence of having been occupied subsequently to the date of registration by the General Medical Council, at least four years, or during a period extending over four winter and four summer sessions, in the acquirement of professional knowledge; and in the case of candidates who shall have pursued the whole of their studies at recognised foreign or colonial universities, upon the production of the several certificates required for their degree by the authorities of such universities, together with a certificate of instruction and proficiency in the practice of Vaccination, and satisfactory evidence of having been occupied, subsequently to the date of passing the Preliminary Examination, at least four years, or during a period extending over four winter and four summer sessions, in the acquirement of professional knowledge.

Professional Examination.—This examination is divided into two parts. The First or Primary Examination, on Anatomy and Physiology, is partly written and partly demonstrative on the recently dissected subject, and on prepared parts of the human body. The Second or Pass Examination, on Surgical Anatomy and the Principles and Practice of Surgery, Medicine, and Midwifery,[24] is partly written, partly oral, and partly on the practical use of surgical apparatus and the practical examination of patients.

The Primary Examinations are held in the months of January, April, May, July, and October, and the Pass Examinations in the months of January, April, July, and October. Candidates will not be admitted to the Primary Examination until after the termination of the second winter session of their attendance at a recognised school or schools; nor to the Pass or Surgical Examination until after the termination of the fourth year of their professional education. The fee of £5 5*s.*, paid prior to the first admission to the Primary Examination, is retained whether the candidate pass or fail to pass the examination, but is allowed as part of the whole fee of £22[25] payable for the diploma. A candidate, after failure at any Primary Examination, is required, on admission to any subsequent Primary Examination, to pay a further fee of £3 3*s.*, which is retained, whether he pass or fail to pass the examination, and which further fee is not allowed as part of the whole fee of £22 for diploma.

The fee of £16 15*s.* is payable prior to each admission to the Pass Examination; but on each occasion of failure the balance of £11 10*s.* is returned to the candidate. A candidate, having entered his name for either the Primary or Pass Examination, who shall fail to attend, will not be allowed to present himself for examination within the period of three months from the date at which he shall have failed so to attend. A candidate referrred on the Pass Examination is required, unless the Court of Examiners shall otherwise determine, to produce, prior to his admission to re-examination, a certificate of at least six months' further attendance on the surgical practice of a recognised hospital, together with lectures on clinical surgery, subsequently to the date of his reference.

[19] The certificates of attendance on the several courses of lectures must include evidence that the student has attended the practical instructions and examinations of his teacher in each course.

[20] The certificate of instruction in vaccination must be such as will qualify its holder to contract as a Public Vaccinator under the Regulations at the time in force of the Local Government Board.

[21] The winter session comprises a period of six months, and, in England, commences on the 1st of October and terminates on the 31st of March.

[22] The summer session comprises a period of three months, and, in England, commences on the 1st of May and terminates on the 31st of July.

[23] It is intended that the candidate should receive the instruction required by Clause 10 at an early period of his attendance at the hospital.

[24] Candidates can claim exemption from examination in Medicine and Midwifery under the following conditions—viz.: The production by the candidate of a degree, diploma, or licence in Medicine and Midwifery entitling him to register under the Medical Act of 1858, or a degree, diploma, or licence in Medicine and Midwifery of a colonial or foreign university approved by the Council of the College. A declaration by the candidate, prior to his admission to the Pass Examination, that it is his intention to obtain either of the qualifications in Medicine and Midwifery mentioned in the foregoing paragraph, in which case the diploma of the College will not be issued to him until he shall produce either the said qualification, or proof of having passed the several examinations entitling him to receive the same.

[25] This sum of £22 is exclusive of the fee of £2 paid for the Preliminary Examination.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGE OF PHYSICIANS OF LONDON AND THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

Regulations relating to the several Examinations applicable to Candidates who commenced their Professional Education on or after the 1st of October, 1884.

Any candidate who desires to obtain both the licence of the Royal College of Physicians of London and the diploma of Member of the Royal College of Surgeons of England is required to comply with the following regulations, and to pass the examinations hereinafter set forth. Every such candidate who shall commence professional study on or after Oct. 1st, 1884, will be required, at the times prescribed for the respective examinations, to produce satisfactory evidence—1. Of having been registered as a medical student by the General Medical Council. 2. Of having been engaged in professional studies at least forty-five months, during which not less than three winter sessions and two summer sessions shall have been passed at one or more of the Medical Schools recognised by the two Colleges. 3. Of having received instruction in the following subjects: (*a*) Chemistry, including Chemical Physics, meaning thereby Heat, Light, and Electricity; (*b*) Practical Chemistry; (*c*) Materia Medica; (*d*) Pharmacy. 4. Of having performed Dissections at a recognised medical school during not less than twelve months. 5. Of having attended, at a recognised medical school—(*a*) A course of lectures on Anatomy during not less than six months, or one winter session; (*b*) a course of lectures on General Anatomy and Physiology during not less than six months, or one winter session; (*c*) a separate practical course of General Anatomy and Physiology during not less than three months. 6. Of having attended at a recognised medical school—(*a*) a course of lectures on Medicine during not less than six months, or one winter session; (*b*) a course of lectures on Surgery during not less than six months, or one winter session; (*c*) a course of lectures on Midwifery and Diseases peculiar to Women during not less than three months; (*d*) systematic practical instruction in Medicine, Surgery, and Midwifery; (*e*) a course of lectures on Pathological Anatomy during not less than three months; (*f*) demonstrations in the post-mortem room during the whole period of attendance on clinical lectures; (*g*) a course of lectures on Forensic Medicine during not less than three months. 7. Of having attended, at a recognised hospital or hospitals, the practice of Medicine and Surgery during three winter and two summer sessions. 8. Of having attended at a recognised hospital or hospitals during nine months Clinical Lectures on Medicine, and during nine months Clinical Lectures on Surgery, and of having been engaged during a period of three months in the Clinical Study of Diseases peculiar to Women. 9. Of having discharged, after he has passed the Second Examination, the duties of a Medical Clinical Clerk during six months, and of a Surgical Dresser during other six months. 10. Of having received instruction in the practice of Vaccination.

Professional Examinations.—There are three Professional Examinations, called herein the First Examination, the Second Examination, and the Third or Final Examination, each being partly written, partly oral, and partly practical. These examinations will be held in the months of January, April, July, and October, unless otherwise appointed. Every candidate intending to present himself for examination is required to give notice in writing to the registrar of the Royal College of Physicians, or to the secretary of the Royal College of Surgeons, fourteen clear days before the day on which the examination commences, transmitting at the same time the required certificates.

The subjects of the First Examination are—Chemistry, Chemical Physics, Materia Medica, Pharmacy, Elementary Anatomy, and Elementary Physiology. A candidate may take this examination in three parts at different times, or he may present himself for the whole at one time. A candidate will be admitted to the examination on Chemistry and Chemical Physics, Materia Medica, and Pharmacy, on producing evidence of having been registered as a medical student by the General Medical Council, and of having received instruction in Chemistry, Materia Medica, and Pharmacy; but he will not be admitted to the examination on Elementary Anatomy and Elementary Physiology earlier than the end of his first winter session at a medical school. A candidate rejected in one part or more of the First Examination will not be admitted to re-examination until after the lapse of a period of not less than three months from the date of rejection, and he will be re-examined in the subject or subjects in which he has been rejected.

The fees for admission to the First Examination are as follows: for the whole examination, £10 10*s.*; for re-examination after rejection in either of the parts, £3 3*s.*

The subjects of the Second Examination are: Anatomy and Physiology. A candidate may present himself for examination in either of these subjects or parts separately, or in both at one time. A candidate will be admitted to the Second Examination after the lapse of not less than six months from the date of his passing the first examination, on producing evidence of having completed, subsequently to registration as a medical student, eighteen months of professional study at a recognised medical school or schools, and of having complied with the regulations prescribed in Section I., Clauses 4 and 5. A candidate rejected in either part or in both parts of the second examination will not be admitted to re-examination until after the lapse of a period of not less than three months from the date of rejection, and will be re-examined in the subject or subjects in which he has been rejected.

The fees for admission to the second examination are as follows: for the whole examination, £10 10*s.*; for re-examination after rejection in either of the two parts, £3 3*s.*

The subjects of the final examination are: Medicine, including Therapeutics, Medical Anatomy, and Pathology; Surgery, including Surgical Anatomy, and Pathology; Midwifery, and Diseases peculiar to Women. A candidate may present himself for examination in these three subjects or parts separately or at one time. A candidate will be admitted to the third or final examination on producing evidence:—1. Of being twenty-one years of age. 2. Of having passed the second examination. 3. Of having studied Medicine, Surgery, and Midwifery, in accordance with the regulations prescribed in Section 1., Clauses 2 and 6 to 10. The Colleges do not admit to either part of the Third or Final Examination any candidate (not exempted from registration) whose name has not been entered in the Medical Students' Register at least forty-five months, nor till the expiration of two years after his having passed the Second Examination. A candidate rejected in the Third or Final Examination, or in one or more of the three parts into which he may have divided it, will not be admitted to re-examination until after the lapse of a period of not less than six months from the date of rejection, and he will be re-examined in the subject or subjects in which he previously failed to pass. Any candidate who shall have obtained a colonial, Indian, or foreign qualification which entitles him to practise Medicine or Surgery in the country where such qualification has been conferred, after a course of study and examination equivalent to those required by the Regulations of the two Colleges, shall, on production of satisfactory evidence as to age and proficiency in Vaccination, be admissible to the Second and Third Examinations.

The Fees for admission to the Third or Final Examination are as follows: for the whole Examination, £15 15*s.*; for re-examination after rejection in Medicine, £5 5*s.*; for re-examination after rejection in Surgery, £5 5*s*; for re-examination after rejection in Midwifery, £3 3*s.*

THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS OF EDINBURGH, AND FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

The above Colleges and Faculty have made arrangements by which, after one series of examinations, held in Edinburgh or in Glasgow, the student may obtain the diplomas of the three co-operating bodies. The general principle of this joint examination is that it shall be conducted by a board in which each body is represented in those branches which are common to both Medicine and Surgery, but that the College of Physicians shall take exclusive charge of the examination in Medicine, and the College of Surgeons, along with the Faculty of Physicians and Surgeons of Glasgow, of the examination in Surgery.

The three co-operating bodies grant their Single Qualifications only to candidates who are already registered as possessing another and opposite qualification in Medicine or Surgery, as the case may be. The Royal College of Physicians of Edinburgh may, notwithstanding this agreement, grant its licence on examination to candidates already possessed

of one or other of the surgical qualifications mentioned in Schedule A of the Medical Act, 1858; and the Royal College of Surgeons of Edinburgh, and the Faculty of Physicians and Surgeons of Glasgow, may each grant its licence on examination to candidates, already Licentiates of one of the Colleges of Physicians of the United Kingdom, or Graduates in Medicine of a British or Irish University. Copies of the Regulations for the Single Qualification of any of the bodies may be had on application to the respective secretaries.

Professional Education.—Candidates must have been engaged in professional study during forty-five months after passing the examination in General Education,[26] which period will include not less than four winter sessions' or three winter and two summer sessions' attendance at a recognised medical school. At the meeting of the General Medical Council, in May, 1885, it was recommended that hereafter the duration of study should be five years.

The candidate must produce certificates or other satisfactory evidence of having attended the following separate and distinct courses of lectures: Anatomy, Practical Anatomy, Chemistry, Practical or Analytical Chemistry, Materia Medica, Physiology, Practice of Medicine, Clinical Medicine, Principles and Practice of Surgery, Clinical Surgery, Midwifery and the Diseases of Women and Children, Medical Jurisprudence, Pathological Anatomy. The six months' courses delivered in Scotland, with the exception of Clinical Medicine and Clinical Surgery, must consist of not fewer than 100 lectures. The three months' courses must consist of not fewer than 50 lectures. The candidate must also produce the following certificates: (*a*) Of having attended Six Cases of Labour under the superintendence of the practitioner who signs the certificate, who must be a registered medical practitioner. (*b*) Of having attended for three months' instruction in Practical Pharmacy, the certificate to be signed by the teacher, who must be a member of the Pharmaceutical Society of Great Britain, or the superintendent of the laboratory of a public hospital or dispensary, or a registered practitioner who dispenses medicines to his patients, or a teacher of a class of Practical Pharmacy. (*c*) Of having attended for twenty-four months the practice of a public general hospital containing, on an average, at least eighty patients. (*d*) Of having attended for six months (or three months with three months' hospital clerkship), the practice of a public dispensary specially recognised by any of the co-operating bodies; or of having been engaged for six months as visiting assistant to a registered practitioner. (*e*) Of having been instructed by a registered medical practitioner in the Theory and Practice of Vaccination. Candidates shall be subjected to three Professional Examinations, herein called the First Examination, the Second Examination, and the Final Examination, to be conducted at separate times, partly in writing and partly practically and orally.

The First Examination will embrace Chemistry, Practical Chemistry, Elementary Anatomy, and Histology, and will take place not sooner than the end of the first year, including a winter and a summer session. The sum of £5 5*s.* must be paid to the Inspector of Certificates for this examination, not later than 11 A.M. of the Saturday preceding it. This sum will be considered as paid to account of the entire fee of £26 5*s.* payable for the three diplomas. In the case of a candidate being unsuccessful at this examination, he will be readmitted to examination after a prescribed interval on payment of £3 3*s.* if he has failed in all subjects, and £2 2*s.* if he has passed in one or more subjects.

The Second Examination will embrace Anatomy, Physiology, Materia Medica and Pharmacy, and will not take place before the termination of the summer session of the second year of study, including two winter and two summer sessions. The sum of £5 5*s.* must be paid to the Inspector of Certificates for this examination, not later than one week before the day of examination. In case of failure, the candidate will be readmitted to examination after the expiration of the prescribed period on payment of £3 3*s.* if he has failed in all subjects, and £2 2*s.* if he has passed in one or more subjects.

The Final Examination will embrace the Principles and Practice of Medicine (including Therapeutics, Medical Anatomy and Pathology), Clinical Medicine, the Principles and Practice of Surgery (including Surgical Anatomy, Operative Surgery and Surgical Pathology), Clinical Surgery, Midwifery (including Gynæcology), Medical Jurisprudence, and Hygiene, and it will not take place before the termination of the full period of study. Every candidate must produce to the inspector, Mr. James Robertson, solicitor, 4, Lindsay-place (George IV. Bridge), Edinburgh, or to Mr. Alexander Duncan, Faculty Hall, 242, St. Vincent-street, Glasgow (1) satisfactory evidence of his having attained the age of twenty-one years; (2) a certificate of his registration in the books of the General Medical Council (see Chap. IV.); (3) the certificates of the classes above enumerated. Of the fee payable for this examination, which is £15 15*s.*, £5 5*s.* must be paid to the inspector not later than one week prior to the examination day, after which no candidate will be entered. The balance of £10 10*s.* must be paid before the candidate is admitted a licentiate of the co-operating bodies. In case of a candidate being unsuccessful at the Final Examination, he will be readmitted to examination after the expiration of the prescribed period, on payment of £5 5*s.*

[26] See the Laws relating to Registration.

KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.

Examinations in the subjects of the First Professional Examination are held quarterly, in January, April, July, and October. Examinations in the subjects of the Final Examination for the licences in Medicine and in Midwifery of the College are held in the week following the first Friday in each month, except August and September. Every candidate for a licence must return his name to the registrar of the College, and lodge with him his certificates, bank (Royal Bank of Ireland) receipt of fees, and his schedule, at least four days before the first Friday in each month.

Licence in Medicine.—Every candidate for the licence of the College to practise Medicine must produce satisfactory evidence 1. Of character, from a Fellow of the College, or from two registered practitioners. 2. Of having passed an examination in general education, held by some one of the examining bodies recognised by the General Medical Council. 3. Of having been engaged during a period of four years in the study of Medicine. 4. Of having attended courses of lectures on the following subjects, at schools recognised by the College: Practical Anatomy, two courses; Physiology or Institutes of Medicine, Chemistry, Practical Chemistry, Materia Medica, Medical Jurisprudence, Practice of Medicine and Pathology, Surgery, and Midwifery—of each one course. 5. Of having attended for twenty-seven months a recognised medico-chirurgical hospital, in which clinical lectures and clinical instruction in Medicine are given, the attendance not to be for more than nine months in any one year—viz, six winter and three summer months. 6. Of having discharged the duties of Medical Clinical Clerk during six months, or of having taken notes, to the satisfaction of the physician in charge of the case, and certified under his hand, of at least six separate medical cases—including different varieties of acute and chronic diseases—in the wards of a recognised hospital; and of having attended, during the whole period of his attendance on hospital practice, Demonstrations in the post-mortem room of a recognised hospital. (This rule to be enforced in the case of all candidates who shall have commenced their professional studies after Sept. 30th, 1883.) 7. Of having studied Fever for not less than three months in a recognised clinical hospital, containing fever wards, and recorded from daily personal observation at least five cases of fever, to the satisfaction of the attending clinical physician, as attested by his signature. The word "Fever" to include the following diseases only—viz., Typhus, Typhoid, Enteric, and Scarlet Fever, Small-pox, Measles.[27] 8. Of having attended Practical Midwifery and Diseases of Women for six months at a lying-in hospital or maternity recognised by the College, or, where such hospital attendance cannot have been obtained during the course of study, of having been engaged in Practical Midwifery under the supervision of a registered practitioner holding public appointments; in either case not less than twenty labour cases must have been actually attended. 9 Of having been engaged in the practical study of Vaccination. 10. Of having lodged the admission fee in the Royal Bank of Ireland, Foster-place, Dublin, to the credit of the College.

[27] Candidates who commenced their hospital studies between September, 1876, and October, 1879, will be required to conform to Rule 6, or to produce evidence of having attended for nine months a hospital which contained fever wards.

The professional examination is divided into two parts: 1. Anatomy, Physiology and Practical Histology, Chemistry, and Materia Medica. 2. Practice of Medicine, Clinical Medicine, Pathology, Medical Jurisprudence, Midwifery, Hygiene, and Therapeutics. Candidates may be examined in the subjects of the first part at the termination of the second year of study, on producing the certificates in the subjects, or in all the subjects of their education, on the completion of their medical studies. No candidate can be examined in the subjects of the first and second parts in the same month.

Candidates qualified as follows are required to undergo the second part only of the professional examination—viz.: (1) Graduates in Medicine of any university in the United Kingdom, or of any foreign university approved by the College; (2) Fellows, Members, or Licentiates of the Royal Colleges of Physicians of London or Edinburgh; (3) Graduates or Licentiates in Surgery; (4) Candidates who, having completed the curriculum laid down above, shall have passed the previous professional examination or examinations (where there are more than one) of any of the licensing medical authorities in the United Kingdom.

The Membership.—Members of the college alone are eligible to the Fellowship. Every candidate for the membership is required to produce satisfactory evidence: 1. Of having attained the age of twenty-five years. 2. Of being a licentiate of this college for three years at least; or a licentiate of one year's standing who shall be a graduate of Arts of a university in the United Kingdom at the time of his obtaining the licence; or a licentiate of one year's standing, who shall be a registered practitioner of seven years' standing at the time of his obtaining the licence. 3. Of professional conduct and moral character, as testified by a Fellow or Member of the college, or by a Fellow of the Royal College of Physicians of London or of Edinburgh. 4. Of not being engaged in trade; of not dispensing medicine, or making any engagement with a chemist, or any other person, for the supply of medicines; and of not practising medicine or surgery in partnership by deed or otherwise. 5. Of having held, during at least six months, the office of resident physician, or resident medical pupil, in a hospital recognised by the college; or of having acted for the same period as clinical clerk in the medical wards of such hospital; or of having been in medical charge, for at least twelve months, of any public institution for the treatment of the sick. 6. Of having lodged the admission fee of 20 guineas in the Royal Bank of Ireland to the credit of the college.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

Candidates for the Letters Testimonial of the College may present themselves either at a Stated or a Special Examination, as hereinafter set forth. Stated Examinations are held in the months of April, July, and November, commencing on dates of which due notice will be given beforehand by the Council of the College. Candidates *cannot be admitted to these examinations unless they be registered pupils.* They will be divided into two classes—junior and senior.

The junior class must produce certificates of—(*a*) having passed a Preliminary Examination recognised by the General Medical Council (into the curriculum of which the Greek language enters as a compulsory subject), and having attended the following lectures: (*b*) three courses of lectures on Anatomy and Physiology; (*c*) three courses of lectures on Practical Anatomy, with dissections; (*d*) two courses of lectures on Chemistry; (*e*) one course of lectures on Materia Medica; (*f*) one course of lectures on Botany; and (*g*) one course of lectures on Forensic Medicine. This class will be examined in Anatomy, Histology, Physiology, Materia Medica, and Chemistry. The fee for this examination is £5 5*s.* (in addition to the registration fee of £5 5*s.*).

The senior class must produce certificates of having attended the following lectures:—(*a*) Three courses of lectures on the Theory and Practice of Surgery; (*b*) one course of lectures on the Practice of Medicine; (*c*) one course of lectures on Midwifery; also certificates of attendance on (*d*) a recognised hospital for three winter and three summer sessions; (*e*) of instruction in Clinical Ophthalmology, three months, and of attendance for one month at the Cowpock Institution or some other institution approved of by the Council, or under the instruction of a public vaccinator specially recognised by this College for that purpose. This class will be examined in Surgery, Operative Surgery on the subject, and Surgical Appliances, Practice of Medicine, Medical Jurisprudence, and Prescriptions. Each of these examinations will be partly written, partly *viva voce*, and partly practical. The fee for the senior class examination is £15 15*s.*, returnable to the candidate in case of rejection, or to be allowed to him in case he presents himself a second time for the same examination. A further fee of £1 1*s.* is to be paid to the registrar.

THE SOCIETY OF APOTHECARIES, LONDON.

EVERY student purposing to study medicine must previously pass a public examination in Arts recognised by the Medical Council, before proceeding with his medical course. Such examination is held in the Hall of the Society four times a year, in March, June, September, and December, and is conducted by means of printed papers. Candidates will be examined in the English and Latin languages, Mathematics, Elementary Mechanics, and one of the following subjects at the option of the candidate—Greek, French, German, Logic, Botany, and Elementary Chemistry. The subjects may be passed at one or more examinations, and no re-examination is required in any subject passed. Registered medical students may present themselves for examination in special subjects if desired. A form of notice accompanying the regulations, obtained from the Society, has to be filled in by the candidate and sent with the fee (one guinea) fourteen days before the examination. Lists of successful candidates are published.

For a licence to practise every candidate will be required to pass two examinations, named respectively the Primary and the Final, each partly written, partly oral, and partly practical. The Primary is held on the first Wednesday and following day of every month. The Final is divided into two parts; Part I. is held on the second and fourth Wednesday and following day of every month; Part II. is held on every Wednesday and Thursday. The course of medical study required for a licence must occupy four years, of which not less than three winter and two summer sessions must be passed at a recognised hospital or school of medicine.

Every candidate intending to offer himself for examination must pay a fee of £6 6*s.*, which in the event of failure will be retained, but no extra fee is required on re-examination. He must also give seven days' notice, and produce the following certificates: (1) for the Primary Examination, a certificate of the commencement of attendance on lectures, and of the course of medical study pursued; (2) for the Final Examination, a certificate of having completed four years' medical study in conformity with the curriculum prescribed, of moral character, and of having attained the age of twenty-one. On such certificates being found correct a card of admission to the examination will be sent, stating the time of attendance. No unsuccessful candidate can be re-examined until the expiration of three months after the Primary and the first part of the Final Examinations respectively, and of six months after the second part.

Every candidate, before he can be qualified for the Primary Examination must have gone through a course of medical study in Chemistry, General and Practical; Botany; Materia Medica; Practical Pharmacy and Dispensing; Anatomy and Physiology, including Dissections and Demonstrations; and Histology, with Demonstrations. The above, including Prescriptions, Practical Chemistry in the Laboratory, and an examination on the living body, form the several subjects of examination for the Primary, which examination may be passed after the second winter session.

For the Final Examination the candidate must give evidence, before he can present himself, that he has gone through the following course of medical study:—Hospital Practice, Surgical and Medical, with Post-mortem Examinations; Principles and Practice of Surgery; Practical Surgery; Clinical Surgical Lectures; Surgical Clinical Clerk or Dresser; Principles and Practice of Medicine; Clinical Medical Lectures; Medical Clinical Clerk; Pathology; Forensic Medicine and Toxicology; Hygiene (its principles and application); Psychological Medicine; Midwifery and Diseases peculiar to Women and Children; Clinical Instruction in the same; attendance on not less than twenty Midwifery cases; and Practical Vaccination.

The Final Examination, which cannot be passed till after the completion of the medical course, and the expiration of forty-five months from registration as medical student, embraces the above; and, in addition, in Part I., Surgical Anatomy,

Surgical Pathology, Surgical instruments and appliances, with a clinical examination of Surgical cases; in Part. II., Obstetric instruments and appliances, Microscopic examinations of morbid structure, and a clinical examination of medical cases. Part I. must precede Part II., and Part II. may be passed any time after Part I.

A candidate who has previously passed either a medical or surgical examination at one of the Medical Colleges or Universities of the United Kingdom is in some cases exempt from certain portions of the examination for the Certificate of Licentiate of this Society. In the case of Graduates of Colonial and Foreign Colleges and Universities, such examinations will be duly considered on their respective merits.

The Society give annually prizes for proficiency in Botany, in Materia Medica, and in Pharmaceutical Chemistry to registered medical students who compete and come up to the required standard, but no student is allowed to present himself for such examination until the end of the third year of his medical studies. Two examinations are held for this purpose in the month of June: the first on the third Thursday, at the Hall of the Society, chiefly written; the second, practical, on the following Saturday in the "Physic Garden" at Chelsea. A written notice must be sent to the Bedell before the 1st of June, which notice must be accompanied by evidence of registration and of attendance on their medical studies. The prizes consist of a gold medal, to be awarded to the candidate who distinguishes himself the most in the examination; and of a silver medal and a book, or books, to the candidate who does so in the next degree.

The examination of candidates for a certificate to act as an assistant in compounding and dispensing medicines, will be as follows: 1. In Translating Prescriptions; in the British Pharmacopœia; in Pharmacy, Pharmaceutical Chemistry, Materia Medica, and Medical Botany. Such examination is held every Thursday in the Hall; seven days' notice must be given, and a fee of two guineas paid, which in the event of failure is retained, no further payment being required for re-examination, before which is allowed three months must have elapsed.

Tickets of admission to the Society's Botanic Gardens at Chelsea, and to the Lectures on Botany when there given, can be had on application at the Hall of the Society.

APOTHECARIES' HALL OF IRELAND.

The Professional Education.—Every candidate for the licence to practise Medicine and Pharmacy must produce certificates to the following effect:—Of having passed a preliminary examination in Arts recognised by the General Medical Council previously to entering on professional study. Of registration in the Medical Students' Register. Of medical study, after registrations of at least five years. The course of medical study after registration should occupy at least five years, if the subjects of Elementary Physics, Chemistry, and Biology are included in that period, or at least four years if a satisfactory examination in these subjects has been passed previously to registration. Of being twenty-one years of age, and of good moral character. Of apprenticeship or pupilage to a qualified apothecary, or of having been engaged at Practical Pharmacy under the supervision of a duly registered medical practitioner, possessing the suitable means of instruction, for a period of twelve months subsequently to having passed the Examination in Arts. Of having duly attended the following courses—viz.: Materia Medica and Pharmacy, during three months; Botany and Zoology, during three months; Chemistry, during six months; Practical Chemistry (in a laboratory), during three months; Anatomy and Physiology, during six months; Practical Anatomy, with Dissections, during twelve months; Medicine (the Principles and Practice), during six months; Surgery (the Principles and Practice), during six months; Pathology, during three months; Midwifery and Diseases peculiar to Women and Children, during six months; Practical Midwifery; attendance on at least twenty cases in a recognised Lying-in Hospital; instruction in Vaccination from a duly registered medical practitioner; Forensic Medicine, during three months; Mental Disease, during three months; Hygiene, one course; attendance on the practice of a recognised medico-chirurgical hospital or hospitals, with the clinical instruction, during at least four winter and three summer sessions; practical instruction, with care of patients, as apprentice, pupil, clinical clerk, or assistant in hospital or dispensary.

The examinations for "the Licence to practise the Profession of Apothecary" is divided into three parts:—The first part comprehends Materia Medica and Pharmacy, Elementary Chemistry, Botany, Zoology, and Human Osteology; the second part Anatomy, Physiology, Histology, and Practical Analytical Chemistry; and the third part Medicine, Surgery, Midwifery, Mental Disease, Forensic Medicine, and Hygiene. The examinations commence on the first Monday in the months of January, April, July, and October, and are conducted by printed papers and orally.

Candidates are eligible for the first part of the Professional Examination at the termination of the second year of study; and candidates for the second part, after having passed the first successfully, at the end of the third year of study; and candidates for the final, after having passed the previous examinations successfully, at the completion of the prescribed courses of professional study. The fee for every examination and re-examination is £2 2s., half to be returned in case of failure. Ten shillings is the charge for the licence of the Hall.

THE ARMY, NAVY, AND INDIAN MEDICAL SERVICES.

Admission into the Army and Indian Medical Services is gained as the result of competitive examination. Candidates for both services must, before being admitted to examination, possess the double qualification to practise Medicine and Surgery, and be registered under the Medical Act, and must also furnish satisfactory certificates of moral character. Candidates for the Army must be between the ages of twenty-one and twenty-eight, in good health, and both parents of unmixed European blood; for the Indian Service, between twenty-two and twenty-eight, of sound bodily health, and natural born subjects of Her Majesty. Both are examined as to physical fitness by a Board of Medical Officers. These conditions being satisfied, the candidate is admitted to the competitive examination, which is usually held in London twice a year, in the months of February and August. The subjects of examination are divided into *compulsory* and *voluntary*. The former comprise Anatomy and Physiology, Surgery, Medicine, including Therapeutics and the Diseases of Women and Children, Chemistry and Pharmacy, and a practical knowledge of Drugs. The eligibility of the candidate for admission into the service is determined by the result of this part of the examination. The *voluntary* subjects are French, German, Comparative Anatomy, Zoology, Natural Philosophy, Physical Geography, and Botany, with especial reference to Materia Medica, and for the Indian service Hindustani. Although the results of the examination on voluntary subjects do not affect the question of the eligibility of the candidate for a commission, they influence his position on the lists, which is determined by the numbers obtained under the two heads conjointly. After having passed this examination, the successful candidates for both services are sent to the Army Medical School at Netley as "surgeons on probation," with the rank of lieutenant and the daily pay of 8s., to go through a four months' course of special instruction in the duties required of them in the service. The staff of the school consists of four professors, all of them men of acknowledged ability and high standing in their special departments. Surgeon-General Sir J. Longmore, Kt., C.B., is Professor of Military Surgery; Deputy-Surgeon-General D. B. Smith, M.D., of Military Medicine; Surgeon-Major de Chaumont, M.D., F.R.S., of Military Hygiene; and Dr. Aitken, F.R.S., of Pathology. To each of these an Army Medical Officer is attached as Assistant-Professor. The lectures on Military Surgery include gunshot and other wounds, transport of sick and wounded, duties of army medical officers in the field, during sieges, and on board troopships and transports, &c. Those on Military Medicine treat of tropical and other diseases to which soldiers are exposed in the course of their service, the mortality and invaliding by disease, in peace and war, at home and abroad. The course of Hygiene comprises the examination of water and air, the general principles of diet, with the quality and adulterations of food and beverages, the sanitary requirements of barracks, hospitals, and camps, the clothing, duties, and exercises of the soldier, and the circumstances affecting his health with the best means of preventing disease, and instruction in the mode of preparing the various statistical and other returns required of the medical officer. The surgeons on probation are detailed for duty in the wards of the hospital, under the Professors and Assistant-Professors of Medicine and Surgery, and receive

practical instruction in the mode of examining recruits. The Surgeons on probation are provided with quarters, and are members of the excellent mess established at Netley. After having passed through the course of instruction they are examined on the subjects taught in the school, and their position on the list recommended for commissions, is determined by the combined results of the competitive and final examinations. At the close of each session five prizes are awarded: the Herbert prize of £20 to the surgeon on probation who has obtained the highest number of marks at the London and Netley examinations conjointly; the Parkes Memorial Bronze Medal to the one who gains the highest number of marks in the examination on Hygiene at Netley, combined with those given for the answers to a special question set on the same subject; the Martin Memorial Gold Medal to the highest number of marks in the final examination on Military Medicine, with the addition of those gained for a special question connected with it; the Montefiore Gold Medal and £20, awarded in the same manner for Military Surgery; and the Montefiore Second Prize, consisting of works on Military Surgery, to the surgeon on probation who obtains the second highest numbers in this branch.

Surgeons are promoted to be Surgeons-Major on completing twelve years' full-pay service, of which three must have been abroad. Before being promoted they will be required to pass an examination intended to test their progress and proficiency in all those branches of knowledge which are essential to their continued efficiency as medical officers, which may be taken at any time between the fifth and tenth year of service. It will embrace the following subjects:—*a.* Surgery, operative and practical, including field surgery and transport of sick and wounded. *b.* Medicine and pathology, including practical pharmacy and modes of prescribing and administering remedial measures, food, drink, &c. *c.* Hygiene, within the limits treated of in "Parkes' Practical Hygiene." *d.* Duties of executive medical officers during peace and war at home and abroad, and at sea, as defined in the various codes of regulations issued for their guidance. Medical officers possessing the following qualifications will be exempted from examination in medicine, surgery, and hygiene respectively: *a.* The Fellowship of any Royal College of Physicians or Surgeons of Great Britain or Ireland, granted under a higher standard of qualification than that for Licentiate or Member, will be accepted in lieu of an examination in medicine and surgery. *b.* The diploma in Hygiene and State Medicine, or any corresponding diploma of any University in Great Britain or Ireland, such diploma being granted after examination, will be accepted in lieu of an examination in this subject. A certificate will be required from a recognised teacher of surgery in any medical school at home or abroad in which operative surgery is taught, showing that the medical officer has gone satisfactorily through a complete course of operative surgery during the period within which the examination must be taken, and that he is a competent operator. A report on any subject of a practical professional character to be selected by the officer himself, and certified to be his own composition, and in his own handwriting, will also be required.

The selection of Surgeons-Major for advancement to the grade of Brigade Surgeon is made on the grounds of ability and merit, in determining which the following points will be considered: The officer to be so selected must have been favourably reported on by the several military and departmental officers under whom he may have served, as set forth in their Annual Confidential Reports. He must be physically fit for general service, and have the necessary qualifying foreign and Indian service under existing rules. He must, before he can be selected for promotion to the grade of Brigade Surgeon, establish before an examining board, appointed for the purpose by the Director-General, his efficiency in the following subjects:—*a.* Hospital organisation and administration in peace and war. *b.* The administration, interior economy, command, and discipline of the Medical Staff Corps and bearer columns. *c.* The relations of the medical to all other departments and corps of the army, as defined by the various Codes of Regulations in force. *d.* Recruiting and invaliding. *e.* The management of sick and wounded in war. *f.* Field Medical organisation. *g.* The transport of the sick and wounded by land and sea. *h.* The medical and surgical equipment and hospital arrangements for an army corps. *i.* The duties and responsibilities of medical officers, quartermasters, and non-commissioned officers and men of the Medical Staff Corps in regard to the charge and supervision of stores and equipments, and the nursing, dieting, and general management of the sick. *k.* The sanitary duties of medical officers in charge of camps and hospitals in the field and at the base of operations. *l.* The sanitary inspection and equipment of hospital ships and troop transports, and all other sanitary duties in camps, garrisons, and quarters. *m.* The origin, progress, and best methods of dealing with outbreaks of epidemic disease among troops under any given circumstance. *n.* The most approved methods of securing the sick, and especially the wounded, against pyæmia, septicæmia, and all other forms of blood-poisoning, and the management and treatment of such outbreaks when they occur. *o.* Questions on operative surgery and practical medicine will also form part of this examination. A medico-topographical report will be required of any district or country in which British troops have been, or are likely to be, actively employed, as well as a sketch of the medical arrangements suitable for an army corps operating in such a district or country, compiled by the officer, and certified to be his own composition and in his own handwriting.

Brigade Surgeons, to be eligible for selection as Deputy Surgeons-General, must have served abroad at least ten years, of which three must have been in India. All officers under the rank of Deputy Surgeon-General are placed on the retired list at the age of fifty-five, and those of that rank and Surgeons-General at the age of sixty.

The regulations above noted respecting the promotion of Surgeons and Surgeons-Major are equally applicable to the Indian Medical Service.

ROYAL NAVY.

The conditions of admission into the Naval Medical Service are the same as those for the Army; but the candidate is also required to declare his readiness to engage for general service, and to proceed on duty abroad whenever required to do so. After having passed the competitive examination in London the successful candidate will receive a commission as surgeon in the Royal Navy, "and will undergo a course of practical instruction in Naval Hygiene at Haslar Hospital." At present Fleet Surgeon Walter Reid, M.D., has been appointed to Haslar "for instruction of surgeons on entry," and Surgeon Gilbert Kirker, M.D., "to assist in instruction of surgeons on entry"; but we have no information as to the length of the course, the conditions under which it is conducted, or the subjects professed to be taught.

Surgeons are promoted to Staff Surgeons after twelve years from date of entry, provided they pass the requisite examination, and Staff Surgeons to Fleet Surgeons after twenty years' service, if recommended by the Director-General. Deputy-Inspectors-General are promoted by selection from the Fleet Surgeons, and Inspectors-General from the Deputy Inspectors-General having three years' foreign, four years' mixed, of which not less than two have been abroad, or five years' home service in such appointments as preclude foreign service, provided they have not refused to go abroad when called upon to do so. Inspectors and Deputy Inspectors-General are retired compulsorily at sixty, and other grades at fifty-five years of age, and all ranks at any time if they have not served for five years. In calculating service for retired pay time on half-pay will be taken as equivalent to one-third service on full-pay.

METROPOLITAN HOSPITALS AND MEDICAL SCHOOLS.

ST. BARTHOLOMEW'S HOSPITAL AND COLLEGE.—The clinical practice of the hospital comprises a service of 750 beds, of which 676 are in the hospital at Smithfield, and 75 are for convalescent patients at Swanley.

Four house-physicians, ten house-surgeons, and a midwifery assistant are appointed annually, each of them holding office for one year, and provided with rooms by the hospital authorities. The ophthalmic house-surgeon is appointed for six months, and is eligible for re-election for a second term of six months. The senior assistant chloroformist and junior assistant chloroformist are appointed annually, and are provided with rooms. Two qualified assistant electricians are appointed every three months. No fee is paid for any of these appointments, and each receives a salary of £25. The clinical clerks, the obstetric clerks, the clerks to the medical out-patients, the dressers to the surgical out-patients, and the dressers in the special departments are chosen from the diligent students. Forty ward-dresserships are given annually to the students who pass the best examination in the subjects of study of the first year. Other ward dresserships may be obtained by payment of the usual fees.

A college is attached to the hospital, in which students can reside, subject to the college regulations.

Foundation and other Prizes.—Open Scholarships in Science of the value of £130 each, tenable for one year, will be competed for in September. Candidates must not be more than twenty-five years of age for one, and twenty-one for the other, and must not have entered to the medical or surgical practice of any metropolitan medical school. The subjects of examination are Physics, Chemistry, Botany, Physiology (not more than four subjects to be taken), and Zoology.—Preliminary Scientific Exhibition (founded 1873). The subjects of examination are identical with those of the Open Scholarship in Science. This Exhibition, of the value of £50, is tenable for one year. The Examination is confined to students of the hospital of less than six months' standing, and will be held in October. The Jeaffreson Exhibition, of the value of £50, and tenable for two years, is awarded after examination in the subjects of General Education. It is now an Open Exhibition. A Senior Scholarship, £50, in Anatomy, Physiology, and Chemistry. Kirke's Scholarship, and Gold Medal in Clinical Medicine, value forty guineas. Lawrence Scholarship, and Gold Medal, of the value of forty guineas (founded in 1873 by the family of the late Sir William Lawrence). Two Brackenbury Scholarships in Medicine and Surgery, £30 each. Junior Scholarships in the subjects of study of the first year: 1st, £50; 2nd, £30; 3rd, £20.

During the last year a prize for Anatomy has been founded by the late Mr. Henry Skinner, in memory of his brother, and by Miss Shuter, in memory of her brother, formerly assistant surgeon to St. Bartholomew's Hospital.

CHARING-CROSS HOSPITAL AND COLLEGE.—Total fees, £94 10*s.*, if paid in a single sum on entry, or £105 if paid in five instalments. General students pay proportionately lower fees, and are admitted without additional fee to the courses of Clinical Medicine and Surgery, to the new classes of systematic practical instruction in Medicine and Surgery, and to the practice of the Royal Westminster Ophthalmic Hospital. They alone are entitled to compete for the Scholarships, Gold Medal, and Pereira Prize.

Preliminary Science Instruction.—Arrangements have been made for students desirous of undergoing a course of instruction in science, such as that required for the Preliminary Scientific (M.B.) Examination of the University of London, to attend at the Normal School of Science, South Kensington.

Two Entrance Scholarships, of the value of £30 and £20 respectively, tenable for one year, are awarded annually in October, after a competitive examination in the following subjects:—*Compulsory*—English, Latin, Mechanics, and Mathematics: *Optional* (only one of which may be selected)—Chemistry, German or French; the subjects being those of the matriculation examination of the University of London. Candidates must give notice of their intention to compete on or before Monday, September 20th, 1886. Two scholarships are open for competition among general students: the Llewellyn Scholarship of £25, for students who have just completed their attendance on lectures; and the Golding Scholarship of £15 for students who have just completed their first year. The Pereira prize of £5 is open to all general students, and is awarded annually for the best clinical reports. The Governors' Gold Medal is given for excellence in clinical work. Silver or Bronze Medals are awarded to the most distinguished students in all classes; and special prizes in the classes of Dental Surgery, Practical Surgery, and Practical Histology.

ST. GEORGE'S HOSPITAL.—Perpetual pupils, by payment of £130 in three instalments, or £125 in one sum, are entitled to admission to the medical and surgical practice; to compete for prizes and exhibitions; to hold the appointment of house-physician and house-surgeon, assistant house-physician, assistant house-surgeon, ophthalmic assistant, registrar's assistant, and to become clinical clerks for two periods of three months each, and dressers for similar periods. Gentlemen are admitted to the hospital practice and lectures required by the College of Physicians and Surgeons and the Society of the Apothecaries on payment of £45 at the commencement of the first year of study, £45 at the commencement of the second year of study, £20 for the third, and £15 for each subsequent year of attendance. These payments entitle the pupil to hold the offices of clinical clerk and dresser for three months each, and to become a candidate for the offices of medical and surgical registrar and demonstrator of anatomy and curator of the museum. These are all salaried offices. The obstetric assistant is resident, with a salary of £100.

Entrance Scholarships.—£125, open to sons of medical men; two of £50 each, open to all students commencing their medical studies; £90, open to students who have passed the Cambridge First M.B.; £75, open to students who have passed the Oxford First M.B. or Cambridge Second M.B.

Prizes.—The William Brown Exhibition of £100 per annum, tenable for two years, open to any perpetual pupil of St. George's who is under twenty-five years of age, and who shall have obtained a diploma or licence entitling him to be registered as a practitioner of medicine or surgery in England, within two years previously to the period fixed for the examination (July). The examination is to test the proficiency of the candidate in Medicine, Midwifery, and Surgery, including Ophthalmic Surgery. The William Brown Exhibition of £40 per annum, tenable for three years, for general fitness for the exercise of the medical profession and for moral conduct, open to perpetual pupils in their fourth year of study. Sir Charles Clarke's Prize (interest of £200 consols) for good conduct; the Brackenbury Prize in Medicine, value nearly £40; the Brackenbury Prize in Surgery, value nearly £40; the Treasurer's Prize, £10 10*s.*; the Thompson Medal; the Bronze Prize for Clinical Surgery; the Acland Prize for Clinical Medicine; the Pollock Prize in Physiology; the Henry Charles Johnson Prize in Anatomy; and General Proficiency Prizes, value £10 10*s.* each, for students of each year.

GUY'S HOSPITAL.—House-physicians and house-surgeons, obstetric residents, dressers, clinical and other clerks, are selected from the students, according to merit, and without payment. The house-physicians, of whom there are three constantly on duty, one as junior and two as seniors, hold office for six months each, the first two months in the former capacity, the other four in the latter. The duty of the junior house-physician is to attend in the medical out-patient room three times a week, in a room adjoining that occupied by the assistant-physician for the day, and prescribe for those patients who are not seen by the assistant-physician. The senior house-physicians are chiefly occupied in the medical wards, and attend to all emergencies that may arise in the absence of the physicians. The house-surgeons, of whom there are also three on duty, hold offices for six months each. During the first two months the house-surgeon has the general superintendence of the Surgical Casualty Department; during the remainder of his time he lives in the hospital, being boarded free of expense. For two months, as second house-surgeon, he has charge of cases in special wards, and assists in the Out-patient Department; and subsequently, as senior house-surgeon, he has, in the absence of the surgeons and assistant-surgeons, the care of the patients in the surgical wards. The dressers

are selected from those gentlemen who have completed their third winter session, and who have been most diligent in the junior appointments. They hold office for six months each. Three are attached to each surgeon. During their week of special duty they reside in the hospital, and board with the house-surgeons. Two obstetric residents reside and are boarded in the hospital.

Scholarships, Prizes, &c.—Open scholarships of the value of £131 5s. in Arts, Latin, Greek, Mathematics, and modern languages. Open Scholarship of £131 5s. in Science. Subjects: Inorganic Chemistry, Zoology, Botany, Physics (these will be competed for on Monday, September 27th). At the end of the summer session: first prize, £50; second prize, £25. Subjects: Anatomy, Physiology, Chemistry, Materia Medica and Botany, or Comparative Anatomy.—For students in their second year: First prize, £25; second prize, £10. Subjects: Anatomy, Physiology. The Sands Cox Scholarship of £15 per annum for three years. Subject: Physiology. The Michael Harris prize of £10 for Anatomy. For students in their third year: First prize, £25; second prize, £10. Subjects: Medical and Surgical Anatomy, Midwifery, and Therapeutics. Fourth year's students: First prize, £25; second prize, £10. Subjects: Medicine, Surgery, Midwifery, and Medical Jurisprudence. For senior students: The Treasurer's Gold Medal in Medicine; the Treasurer's Gold Medal in Surgery; The Gurney Hoare Prize of £25 for Clinical Medicine and Surgery; the Beaney Scholarship of 30 guineas for Pathology; the Mackenzie Bacon Prize of 10 guineas for Ophthalmoscopy; the Mackenzie Bacon Prize of £15 for Nervous Diseases. The Physical Society awards the following prizes: Two of £5 each to the members who send in the best essays on selected subjects; prizes of £10 and £5 for the best papers read before the Society; and one of £5 to the member who has most distinguished himself in the debates of the session.

KING'S COLLEGE.—The physicians' assistants, the physician-accoucheur's assistant, the ophthalmic clinical assistant, the clinical clerks, and the house-surgeons and dressers, are selected by examination from among those matriculated students of the college who are pupils of the hospital. Rooms are provided within the walls of the college for the residence of a limited number of matriculated students. Rooms and commons are provided at the hospital for the resident officers free of charge.

Scholarships.—Warneford Scholarships: Two of £25 per annum for three years for Literature. Science: One of £50 and one of £25 each for two years. Sambrooke: One of £60 and one of £40 for Science. Rabbeth Scholarship of £20 per year for Science. College Scholarships: One of £40 per annum for two years; one of £30 for one year; three of £20 for one year. The Daniell Scholarship, for Chemistry, of the annual value of £20. Sambrooke Registrarships, of the annual value of £50 each, and tenable for two years, are open to all matriculated students who have filled any one of the higher appointments of the hospital, or who have become Associates. The Leathes Prizes, value £7, and the Warneford Prizes, value £40, are given annually amongst the matriculated medical students. Two Medical Clinical Prizes, one of £3 for the winter session, and one of £2 for the summer session, and two Surgical Clinical Prizes, of £3 each, are given. The Todd Medical Clinical Prize consists of a bronze medal and books to the value of £4 4s. The Tanner Prize for Obstetric Medicine, value £10, and the Carter Gold Medal and Prize for Botany, value £15, are given annually in July. Class Prizes, value £3 3s. each, are awarded annually in every subject. A Warneford Scholarship of £25 per annum for two years for third-year subjects is awarded annually to resident students only.

LONDON HOSPITAL AND COLLEGE.—The Medical School of the London Hospital is under the direction of a college board, composed of six members of the hospital staff and six of the house committee. The executive authority is committed to a warden. The hospital, which is the largest in Great Britain, contains nearly 800 beds. Last year the number of in-patients was 8732, out-patients 67,942.

The following Scholarships and Prizes will be offered for competition during the ensuing winter and summer sessions:—Two Entrance Scholarships in Natural Science, of the value of £60 and £40 respectively, will be offered for competition on September 20th, 21st, and 22nd, 1886. The subjects are Physics, Botany, Zoology, and Inorganic Chemistry. The successful candidates must forthwith become full pupils of the hospital and school, if not already entered; and are not eligible to compete for the Buxton Scholarships: -The two Buxton Scholarships, value £30 and £20, will be offered for competition on September 27th, 28th, and 29th, 1886. The subjects are those appointed by the General Council of Medical Education and Registration as the subjects of the Preliminary Examination. A Scholarship, value £25, in Anatomy, Physiology, and Chemistry, will be competed for at the end of the winter session by first and second year students. A Scholarship, value £20, in Anatomy and Physiology for first-year students. (At the commencement of the summer session.) The Letheby Prize, value £30, for Proficiency in Chemistry. (At the end of the summer session.) Open to all full students who have completed their second summer session up to the termination of their fourth year from entrance. A Hospital Scholarship, value £20, for proficiency and zeal in Clinical Medicine. (At the end of the winter session.) A Hospital Scholarship, value £20 for proficiency and zeal in Clinical Surgery. (At the end of the winter session.) A Hospital Scholarship, value £20, for proficiency and zeal in Clinical Obstetrics. (At the end of June.) The Duckworth Nelson Prize, value £10, will be offered biennially for competition at the end of the winter session, and be open to all students on similar conditions to those of the Hospital Scholarships. The subjects of examination will be Practical Medicine and Surgery. The Hutchinson Prize, value £35, will be given triennially to the author of the best essay upon a subject in Clinical Surgery. Candidates must be full students of the hospital who have not been registered more than ten years. Out-patients' Dressers' Prizes. Six prizes, of the aggregate value of £60, will be offered for competition at the end of the winter session. Candidates must pass an examination in Minor Surgery, have dressed diligently for twelve months, and have passed the Primary Examination of the Royal College of Surgeons. Two Dissection Prizes, value £6 and £4. Special classes are held throughout the year for the Preliminary Scientific Intermediate M.B. Examinations of the University of London and for the Primary and Pass Examinations for the Fellowship of the Royal College of Surgeons. Special entries can also be made for Medical and Surgical Practice, the Operative Surgery classes, &c. The very extensive alterations that have been made to the school premises during the past year will afford complete provision for the teaching of all branches of medical science, the accommodation now afforded being more than double that which was provided in the old buildings.

ST. MARY'S HOSPITAL.—There are five resident medical officers, four of whom are appointed for twelve months, and one, the obstetric officer, for six months, who board free of expense in the hospital. These appointments are awarded after competition, without additional fee. Two Demonstrators of Anatomy are appointed annually, with a salary of £70 and £50 respectively; a Demonstrator of Physiology, at £100 a year; and a Demonstrator of Histology, at £50 a year. All these officers are eligible for re-election. There is also a Demonstratorship in Pathological Anatomy, of the value of £15, and tenable for six months; the holder of this scholarship will assist the pathologist in the discharge of his duties in the museum and dead-house. Two Prosectors of Anatomy and two Assistant Demonstrators of Physiology are appointed annually, and receive a certificate and £5 each for satisfactory service in their respective departments. All students are required to perform the duties of clinical clerk and dresser during the last two years of their curriculum. Students of the third year and of subsequent years are also appointed as clerks and dressers to assist the physicians and surgeons in charge of the out-patients. In addition to the instruction given in the wards daily, distinct Clinical Lectures are given on Fridays throughout the academical year at 3.30 P.M. The hospital contains 270 beds, 130 of which are devoted to medical and 140 to surgical cases. Two wards are appropriated to the Diseases of Children, and one to those of Women; beds are also provided for Ophthalmic, Aural, and Cutaneous cases.

Scholarships, Prizes, and Appointments: Scholarships offered for open competition previously to entering at the Medical School.—Entrance Scholarships: The following will be offered for competition on Sept. 30th and Oct. 1st:—One Scholarship in Natural Science, of the value of 100 guineas, open to any gentleman who has not completed a

winter session of study at a medical school. Three Scholarships in Natural Science, each of the value of 50 guineas, under the same conditions. One Scholarship of the value of 100 guineas, open to students from Epsom College, being sons of medical men, and who have not completed a winter session of study at a medical school. Two Scholarships, each of 50 guineas, open to students from the Universities of Oxford, Cambridge, or other University, who have not entered at any London medical school.

In addition to the Open Entrance Scholarships, Class Prizes, and usual Appointments, Scholarships will be offered for competition at the end of each year, open to all pupils. These Scholarships are of the value of £20, £25, and £30, for the first, second, and third years respectively.

A residence for students, 33, Westbourne-terrace, W, in connexion with the hospital, is under the charge of a warden (Dr. Robert Maguire), and the dean is prepared to receive applications from students desiring to enter upon residence during the ensuing session. Terms: 90 guineas for the academical year, payable 30 guineas in advance, on Oct. 1st, Jan. 1st, and May 1st, to include special instruction by the demonstrators on four days a week.

MIDDLESEX HOSPITAL.—There is a special Cancer Department, affording accommodation for thirty-three in-patients, whose period of residence in the hospital is unlimited. Classes, open to all the students, are held for practical instruction in medicine, midwifery, in the microscopical examination of healthy and diseased tissues, and also in the application of bandages and other surgical apparatus. Students are allowed to take out to read at their own homes the books from the large and carefully selected medical library of the school. The museum has recently been rearranged, and a complete catalogue prepared of the various specimens. Two Entrance Scholarships, of the annual value of £50 and £30, and tenable for two years, are offered for competition at the commencement of the winter session. An Exhibition in Elementary Anatomy, Osteology, and Physiology, value £10 10s., is awarded to students at the end of their first year. The Lyell Medal is awarded annually for proficiency in Surgical Anatomy and Practical Surgery. The Hetley Prize is awarded annually for Clinical proficiency. Two Broderip Scholarships, of the annual value of £30 and £20, tenable for two years, are awarded to those students who pass the best examination at the bedside and the post-mortem room. The Murray Medal and Scholarship, founded in connexion with the University of Aberdeen, is awarded every third year to a student of this hospital; it will be next awarded in May, 1889. The Governors' Prize of 20 guineas is also awarded annually to the student after his third winter session who shall pass the best clinical examination in the out-patient departments. Valuable class prizes are also given, and fourteen resident clinical appointments are annually awarded, after competitive examination, to students who have completed their education and complied with the regulations of the school.

Arrangements have been made for students desirous of undergoing a course of instruction in Science, such as that required for the Preliminary Scientific (M.B.) Examination of the University of London, to attend such a course at the Normal School of Science, South Kensington. Fee for the whole course, £35. Students who enter for this course will be allowed a deduction of £20 on the fees for the medical curriculum.

ST. THOMAS'S HOSPITAL.—*Prizes and Appointments for the year 1886-87.*—For First-year's students: Two Entrance Scholarships in Natural Science of the value of £100 and £60 respectively, open to all first-year's students, will be awarded during the first week in October, after an examination in Physics, Chemistry, and either Botany or Zoology at the option of the candidate; the William Tite Scholarship, the proceeds of £1000 Consols (£30 per annum), is awarded each year; also prizes of £20 and £10; summer £15 and £10. For second-year's students: The Peacock Scholarship of 50 guineas, and the Musgrove Scholarship of 40 guineas, are awarded biennially to the students who shall take the highest place in the first-class list in the examinations at the end of the second winter session; they are tenable for two years, provided the holder obtains a place in the first class in the subsequent examinations: making the winter prizes £42, £20 and £10; summer, £15 and £10; with the dresserships and the clinical clerkships. For third-year's students (winter): Second Tenure of Scholarship £42, and prizes of £20, £15, and £10; summer, £15 and £10. Clinical clerks and dressers are selected according to merit. The Grainger Testimonial Prize of £15 is awarded annually to students, who shall be from three to six years' standing, for the best Anatomical or Physiological Essay, to be illustrated by preparations and dissections. The Cheselden Medal for Surgery and Surgical Anatomy, and the Mead Medal for Practical Medicine, are awarded annually to fourth-year's students. The Solly Medal, with a prize from 10 to 20 guineas, will be awarded biennially to a student of the third, fourth, fifth, or sixth year, for the best report of Surgical cases. The next award will be made in 1888. The Treasurer's Gold Medal, for general proficiency and good conduct, is awarded annually to a fourth-year's student.

Classes in Practical and Operative Surgery are held four times a week for six weeks prior to the final examinations of the Examining Board in January, April, and July. In connexion with these classes, Clinical Instruction is given in the wards by the resident assistant-surgeon, and a course of demonstrations on Museum Specimens is given by the curator, Mr. Shattock.

UNIVERSITY COLLEGE, LONDON.—*Composition Fees.*—1. For the entire medical education required by the Examining Board in England and the Society of Apothecaries, 125 guineas, if paid in one sum at the commencement of the course; 130 guineas, if paid by instalments, as follows—first year, 60 guineas; second year, 50 guineas; third year, 20 guineas. 2. For the classes required by the Examining Board to be attended at a medical school, 100 guineas, if paid in one sum; 105 guineas, if paid by instalments, as follows—first year, 50 guineas; second year, 35 guineas; third year, 20 guineas. 3. For the whole course of instruction for the Intermediate Examination in Medicine of the University of London, 50 guineas. 4. For the course of instruction for the Final M.B. Examination of the University of London, 70 guineas, if paid in one sum; 72 guineas, if paid by instalments, as follows—first year, 40 guineas; second year, 32 guineas. 5. Composition fee for Dental Students, 60 guineas.

Exhibitions, Prizes, &c.—Three Entrance Exhibitions, of the respective values of £100, £60, and £40 per annum, tenable for one year, are annually awarded, upon examination by printed papers, to gentlemen who are about to commence their first winter attendance in a medical school. The subjects of the examinations are—Chemistry, Physics, Botany, and Zoology. The next examination will take place at the College on September 29th and 30th. The Atkinson Morley Surgical Scholarship of £45, tenable for three years, is annually awarded to the student who, upon examination, is found to possess the greatest proficiency in the Theory and Practice of Surgery. The Sharpey Physiological Scholarship of about £105 per annum, tenable for three years, for proficiency in Biological Science. Filliter Exhibition: a prize of £30 is awarded annually, in July, to the most proficient student in the class of Pathological Anatomy. An Atchison Scholarship, value about £55 per annum, tenable for two years. The Erichsen Prize, a surgeon's operating case of the value of £10 10s., awarded yearly to the student of the class of Practical Surgery who shall most distinguish himself by manipulative skill. The Morris Bursary of £25 a year, tenable for two years. Besides the above, gold and silver medals, and other prizes, are awarded in each class.

WESTMINSTER HOSPITAL.—The hospital contains upwards of 200 beds. There are separate departments for Diseases of the Eye, Ear, Skin, Teeth, and Throat, and for Diseases of Women. The Anatomical Museum is constantly open to the students. There are also a Pathological Museum and a Materia Medica Museum.

A curator of the museum and pathologist, with a salary of 50 guineas, and a medical and surgical registrar, are appointed annually, each with a salary of £40. Two house-physicians, two house-surgeons, and a resident obstetric assistant are appointed for six months after examination, and are provided with rooms and commons. The Senior house-physician, who is also the chloroformist to the hospital, and the senior house-surgeon who performs special duties, receive in addition an honorarium of 20 guineas each. Clinical assistants to the physicians and surgeons, and to the officers in charge of special departments, are appointed from students of the fourth year.

Scholarships and Prizes.—The Guthrie and Entrance Scholarship, on alternate years, each £40 a year, and one Entrance Scholarship value £40. Entrance Scholarship, summer session, value £40. The Treasurers' Prize, an exhibition in Anatomy, Physiology, and Chemistry, value £10 10s., tenable for one year for first-year's men. The President's Prize, a Scholarship in Anatomy, Histology, and Physiology, value £21, given by his Grace the Duke of Westminster, President of the Hospital, to a student of the second year (to be styled Assistant Demonstrator). At the end of the fourth winter session, prizes of £5 each (books or instruments) in Clinical Medicine and Clinical Surgery. Frederick Bird Medal and Prize, value £15. Subjects of examination: Medicine, Midwifery, Diseases of Women and Children, and Pathology. Chadwick Prize for General Proficiency, £21 (books or instruments), to the most meritorious student or students of any year not exceeding the fifth. In most of the classes special prizes, value about 2 guineas each, are given by the lecturers.

GREAT NORTHERN CENTRAL HOSPITAL, Caledonian-road, Consulting Surgeon: Frederick Le Gros Clark. Physicians. Drs. Cholmeley, Cook, Burnet, Beale, and Beevor. Obstetric Physicians: Drs. Gustavus C. P. Murray and Fancourt Barnes. Surgeons: Messrs. W. Adams, W. Spencer Watson, J. Macready, C. B. Lockwood, and G. H. Makins. Ophthalmic Surgeon: Mr. Jonathan Hutchinson, jun. Aural Surgeon: Mr. A. E. Cumberbatch. Choloformist: Mr. George Eastes. Dental Surgeon: Mr. E. Keen. House-Surgeon: Mr. A. Frank Whitwell. House-Physician: Mr. Donald Gunn. Dispenser: Mr. J. F. Dunstan.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—Consulting Physicians: Dr. C. J. B. Williams, F.R.S., Dr. W. H. Walshe, Dr. R. Quain, F.R.S., Dr. J. E. Pollock. Consulting Surgeon: Professor John Marshall, F.R.S. Physicians: Drs. E. S. Thompson, C. T. Williams, R. D. Powell, J. Tatham, R. E. Thompson, and F. Roberts. Surgeon: Mr. R. J. Godlee, F.R.C.S. Assistant-Physicians: Drs. T. H. Green, J. M. Bruce, J. Fowler, P. Kidd, C. Y. Biss, and C. T. Acland. Pathologist: Dr. P. Kidd. Dental Surgeon: Mr. C. J. Noble. Resident Medical Officer: Dr. H. D. Waugh. Secretary: Mr. H. Dobbin. Four Clinical Assistants reside in the hospital for a period of six months. Pupils are admitted to the practice of the hospital: terms £3 3s. for three months; six months, £5 5s.; perpetual, £10 10s. Lectures and Clinical Demonstrations are given throughout the year by members of the medical staff. The medical practice of the hospital is recognised by the University of London, the Apothecaries' Company, and the Army and Navy and Indian Medical Boards. The hospital contains 321 beds in the two buildings.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City-road.—Established 1814. Consulting Physician: Dr. Horace Dobell. Physicians: Drs. Hensley, Gilbart-Smith, Finlay, White, Pringle, and Oswald Browne. Assistant-Physicians: Drs. Arthur Davies, Herbert Habershon, and Edward Stewart. Consulting Surgeon: Mr. Jonathan Hutchinson. Surgeon: Mr. A. Pearce Gould. House-Physicians: Messrs. Harrold Simmons and Frank T. Wethered. In-patients (1885), 122; out-patients (1885) 23,030. This hospital has recently been enlarged by the addition of a very complete out-patients' department, and also by the erection of a new wing, which will provide accommodation for 80 in-patients.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury.—The new hospital, with the Finchley Branch, contains 180 beds and cots. The physicians attend every Monday, Tuesday, Wednesday, and Friday, at 2.30 P.M. In- and out-patients' practice and electrical room treatment at that hour. Physicians: Drs. Ramskill, Radcliffe, Hughlings Jackson, and Buzzard. Physicians for out-patients: Drs. H. Charlton Bastian, W. R. Gowers, and Ferrier. Assistant-Physicians: Drs. Ormerod and Beevor. Surgeons: W. Adams and Victor Horsley. Ophthalmic Surgeons: R. Brudenell Carter and Marcus Gunn. Aural Surgeon: A. E. Cumberbatch. House-Physicians: T. Wilson and F. Stedman. Medical practitioners and senior students may attend the practice after signing their names in the clerk's office.

ROYAL LONDON OPHTHALMIC HOSPITAL, Moorfields.—The hospital, founded in 1804, and considerably enlarged in 1870, now contains 100 beds for patients, which were occupied during last year by over 2000 persons. The out-patients are yearly over 20,000; attendances, 130,000. Operations are performed daily from half-past ten to one o'clock, and three surgeons attend on each day. Students are admitted to the practice. Fees for six months, £3 3s.; perpetual, £5 5s. Demonstrations and lectures are given during the winter. Students of the hospital are eligible for the office of house-surgeon, or may be appointed clinical assistants. The Secretary, Mr. Robert Newstead, will furnish further information, as may be desired.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL, King William-street, West Strand.—The hospital contains 50 beds; and the patients, who number 10,000 annually, are seen and operations performed daily at 2 o'clock. The following are the days of attendance of the surgeons: Mr. Power and Mr. Frost, Monday and Friday; Mr. Rouse and Mr. Hartridge, Tuesday and Saturday; Mr. Macnamara, Monday and Thursday; Mr. Cowell and Mr. Juler, Wednesday and Saturday. The practice of the hospital is open to students. Fees for six months, £3 3s.; perpetual, £5 5s. Students of the hospital are eligible for the post of house-surgeon. Special demonstrations and lectures will be given during the session. Secretary, Mr. T. Beattie-Campbell.

ROYAL ORTHOPÆDIC HOSPITAL, 297, Oxford-street.—Surgeons: Messrs. B. E. Brodhurst, H. A. Reeves, Charles Read, and William E. Balkwill. Assistant-Surgeon: Mr. H. F. Baker. House-Surgeon: Mr. W. B. Thomas. Secretary: Mr. Maskell. Operations on Mondays at 2 P.M. The hospital is open to all legally qualified practitioners. Pupils are admitted to witness the practice of the hospital on the following terms: six months, £3 3s.; twelve months, £5 5s.; perpetual, £10 10s.

DENTAL HOSPITAL OF LONDON MEDICAL SCHOOL, Leicester-square.—Lectures are delivered in winter on Mechanical Dentistry by Dr. J. Walker, on Wednesdays at 5 P.M. In summer, by Mr. Hutchinson, on Dental Surgery and Pathology, on Tuesdays and Fridays at 8 A.M., and by Mr. Arthur Underwood, on Dental Anatomy and Physiology (Human and Comparative), on Wednesdays and Saturdays, at 8 A.M. *Fees:* General fee for special lectures required by the curriculum, £15 15s.; fees for two years' hospital practice required by the curriculum, £15 15s.; total fees for lectures and practice, £31 10s. Hospital Surgeons: Messrs. Canton, Gregson, Hepburn, Storer Bennett, Underwood, and Woodhouse. Assistant-Surgeons: Messrs. Hern, Matheson, Parkinson, Read, Rogers, and Truman. Anæsthetists: Messrs. Braine, Bailey, Bird, and Mills. Assistant-Anæsthetists: Drs. Brunton and Hewitt. House-Surgeon: Mr. C. F. Rilot. Assistant House-Surgeons: Messrs. F. Colyer and R. W. Rouw. Medical Tutor: Mr. W. Paterson. The winter session will commence October 4th. All communications to be addressed to Mr. Morton Smale, Dean.

SEAMEN'S HOSPITAL (late *Dreadnought*), Greenwich.—This institution is established for the relief of seamen of all nations. Casualties are received at all hours. Apartments are provided in the house of the Principal Medical Officer for students. Honorary Consulting Physicians: Dr. Robert Barnes, F.R.C.P., and Dr. Richard Quain, F.R.C.P. Visiting Physicians: Dr. John Curnow, F.R.C.P., and Dr. Herbert Tyrrell Griffiths, M.R.C.P. Honorary Consulting Surgeon: Vacant. Visiting Surgeon: Mr. G. Robertson Turner, F.R.C.S. Medical Officer, Well-street Dispensary: Mr. C. E. Cotes, F.R.C.S. Principal Medical Officer: Mr. W. Johnson Smith, F.R.C.S. House-Physician: Mr. E. H. Booth, M.B. House-Surgeon: Mr. C. Stuart Spong. Secretary: Mr. W. Thomas Evans.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, Queen-square, W.C., and Cromwell House, Highgate.—Physicians: Drs. W. B. Cheadle, Sturges, and Barlow. Assistant-Physicians: Drs. R. J. Lee, D. B. Lees, Montague Lubbuck, Abercrombie, and Angel Money. Surgeons: Mr. Howard Marsh, Mr. Edmund Owen, Mr. J. H. Morgan, Mr. Bernard Pitts, and Mr. Arbuthnot Lane. Ophthalmic Surgeon: Mr. R. Marcus Gunn. Surgeon-Dentist: Mr. A. Cartwright. Secretary: Mr. Adrian Hope. There are now 121 beds in the hospital, Great Ormond-street, and 52 beds at the country branch; total 173. In-patients last year, 1144; out-patients, 14,287. The practice at the hospital has recently been thrown open gratuitously to the pupils of the different hospitals and medical schools of London on conditions which may be ascertained of the Secretary.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL, Marylebone-road, London, W.—This hospital has been recently enlarged, and is in full operation. It receives nearly 700

patients annually, besides having a large out-patient maternity. The pupils are permitted to see the practice in both departments. Medical pupils are received at all times of the year. Pupils enjoy unusual opportunities of seeing obstetric complications and operative midwifery, on account of the very large number of primiparous cases—upwards of three-fourths of the total admissions. Clinical instruction is given on the more important cases that present themselves in both departments. Certificates of attendance at this hospital are received by all universities, colleges, and licensing bodies; and a diploma is granted in Midwifery. Monthly nurses and midwives are received for training. For further particulars, applications should be made to the Secretary, at the hospital.

ROYAL HOSPITAL FOR CHILDREN AND WOMEN, Waterloo-bridge-road. — Instituted 1816. Consulting Physicians: Dr. Wilks and Dr. John Williams. Physicians: Drs. W. A. Duncan, W. B. Haddon, W. Park, and W. R. Dakin. Surgeon: Mr. H. C. Jacobson. Assistant-Surgeon: Mr. E. Overman Day. Surgeon-Dentist: Mr. W. Whitehouse. Resident Medical Officer: E. H. Freeland. Secretary: Mr. R. G. Kestin. Advanced students in medicine, and such practitioners as may desire it, are permitted to attend the practice of this hospital gratis. If a certificate signifying such attendance be required, the sum of £5 5s. must be paid to the physicians and surgeons in ordinary conjointly.

HOSPITAL FOR WOMEN, Soho-square, W., Consulting Physician: Dr. Protheroe Smith. Physicians: Drs. Carter, Richard T. Smith, Holland, and Mansell-Moullin. Surgeon: Mr. H. A. Reeves. Assistant-Physicians: Drs. Bedford Fenwick and Oliver. Assistant-Surgeon: Mr. S. Osborne. Pathologist and Registrar: Dr. Norman Dalton. Anæsthetist: Dr. Dudley Buxton. In connexion with this institution there has for some years been a well-organised Clinical Department, which has lately been enlarged under the title of the London School of Gynæcology. To meet the want increasingly felt by medical men of an accurate knowledge of the ordinary diseases of women, ten gentlemen are appointed every three months to act as clinical assistants to the physicians and surgeons seeing out- and in-door patients. The appointments are nominally "open to qualified medical men and to students of medicine after their third year," but in the selection of candidates preference is naturally given to gentlemen already engaged in practice. The large numbers of out-patients afford quite unrivalled opportunities for practical instruction in the use of gynæcological instruments, and for the study of diseases peculiar to women. A course of lectures on the Anatomy and Physiology of the Female Pelvic Organs is given during each quarter by a member of the Staff. Clinical Lectures are given in the Operating Theatre on alternate Thursday afternoons at 3.30 P.M. throughout the winter and summer sessions. Valuable prizes are given, after examination, annually, open to past and present clinical assistants. Fee for the three months' course, £5 5s. Any further information can be obtained by letter, addressed to the Dean at the hospital.
